GLEANINGS IN BEE CULTURE
A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS
ILLUSTRATED SEMI-MONTHLY
PUBLISHED BY A. I. ROOT
$1.00 PER YEAR MEDINA OHIO

Vol. XX. JANUARY 1, 1892. No. 1.

STRAY STRAWS

FROM DR. C. C. MILLER.

THE BEST MOTH-EXCLUDER, the *Bee-keepers' Magazine* says, is the bee. Right.

MOST BEESWAX, R. F. Holtermann thinks, is injured by too much heating in rendering.

NAPTHALINE, the *C. B. J.* suggests, when used in a hive, may injure the flavor of the honey.

THE *Bee-keepers' Magazine* is the latest name of the monthly started in Minnesota that was first *The Bee Journal* and then *Northwestern Bee Journal.*

EIGHT YEARS the Bee-keepers' Union has existed, and the same officers have been elected each year. The manager urges the election of new men. He's right.

AND NOW it's out what ails Hasty. He's a posy-lover! Aren't you ashamed, Hasty? But if the bees like flowers so well, what else can be expected of their owners?

THE *C. B. J.* proposes to open a free intelligence office for those who want to serve an apprenticespip at bee-keeping, and for those who want such apprentices.

I WONDER the senior editor didn't start a carp-pond with the waste from that artesian well in Dakota I suppose he'll erect an artesian well in Medina when he gets home.

STRAY STRAWS in last number of GLEANINGS says each State at the World's Fair would have ten square feet for a bee-show. The types or I made a mistake. It should be ten feet square.

"DANGEROUS ADVICE" is what the *C. B. J.* terms the advice of the *B. B. J.* to disinfect the combs of foul-broody stocks with the fumes of burning sulphur, said combs to be then used as safe.

A MAMMOTH CONVENTION of bee-keepers at the World's Fair, lasting one or two weeks, with all the great bee-lights of Europe and America present, is proposed by D. A. Jones. Why not?

IN FRANCE they are cultivating a plant parasite that is death to the white grub, the larva of the May beetle. What a blessing if we could have some parasite for wax-moths and foul-brood germs!

THE *A. B. J.* has no less distinguished a correspondent than Thos. Wm. Cowan, of the *B. B. J.* The occasion was an article in favor of Punics, and Mr. Cowan rather more than hints that there are no such bees.

SO, MRS. HARRISON, bees "have a picker but no biter." Well, well; Root, Cheshire, and all the authorities will have to correct their books. Say, do bees use their "pickers" down your way to climb out of feeders?

ALPAUGH'S NEW METHOD of handling bees comes in for a good deal of discussion in *C. B. J.*, and great things are claimed for it; but so far it is a profound secret, and Mr. Alpaugh himself is expressively silent about it.

THE BEE-KEEPERS' UNION is on the up grade. Fifty per cent increase of members in one year! It's doing good work, and the membership ought to more than double for the coming year. Send $1 to T. G. Newman, and become a member. It may save you $100.

SCIENTISTS must be suppressed along with anarchists and all other *ists.* Here they've gone and invented microbes, bacteria, and things of that sort, to give us grip, foul brood, and every thing else. Fifty years ago the air wasn't full of such things, and people got along better without them.

SECRETARY HUTCHINSON, speaking of the action of the Chicago convention relative to grading comb honey, says, in his report, "The adoption of these rules was really the most important work done by the convention, and perhaps the most important that will be done by any convention this year."

VASELINE, the *C. B. J.* thinks, might be a good thing to paint lightly over a queen to be introduced, with the supposition that, as it drives robbers away, it would drive away from the queen any bees that might try to sting her. I'd rather try it on a cheap queen first. It *might* have just the opposite effect.

A CORRESPONDENT says he has been watching GLEANINGS in vain to see what was my crop of honey the past year. From 236 colonies I got about 8600 lbs. of comb honey, or 36½ lbs. per colony. Although living not 20 miles away, he took only 150 lbs. from 80 colonies, or about 2 lbs. per colony. But he sometimes gets honey, I think, when I fail.

AFTER ZERO WEATHER it is again milder, and Dec. 20 bees could fly outdoors, the first time since the last week in October. So you see there was nothing gained by leaving them out after the last of October, unless they were left out till Dec. 20, and I'm afraid the flight on that day would not counterbalance the harm done by the previous zero weather.

WHAT MAKES people paint the inside woodwork of their houses, when pine or any other wood is so much handsomer, and costs no more finished off in its natural color? I'd rather have it finished with nothing but linseed oil rubbed on with a rag than to have the finest job of painting. But I'd like still more to have something better than the oil and rag.

GRADING HONEY is one of the things that I suspect will not be settled in a day, and it may be well to thoroughly discuss the matter in print. I'm anxiously waiting to see what was done about it at Albany, but I suspect it will still be open for discussion. Unless they modia good thing, and will prove a boon to bee-keepers. It is likely that further improvements will be made in the near future; and if he will adopt such suggestions as are valuable, much will be gained. In these days of study and invention, one man can hardly hope to know it all; in fact, most of the implements used in bee-keeping are the joint invention of many.

There is one thing more that I wish to mention in connection with the hiver; and that is, that we often have hives containing comb and honey that we wish to put our first swarms into. Now, it will not do to place such hives to receive the swarms, on account of moths and robbers. In such cases I use an empty super on top (how would it look if placed on the side?). Now, when the swarm is in the air, and the queen in the upper part of the swarmer, I unhook it from the super and slip a piece of tin behind it, so the queen can not escape. Remove the old hive, and place the one with combs in on the old stand, and the part of the swarmer with queen in, in front of the entrance, removing the tin. It is not best to remove the swarmer for several days, as the bees may take a notion to abscond. I have several times liberated the queen an hour or two after the swarm was hived in this way, but soon found them all in the air again, and had my work to do over.

I can fully agree with Mr. Alley, that the swarmer greatly lessens and retards swarming. On this account, as well as not tolerating a horde of drones in every hive, bees will gather more honey per colony with the swarmers than without them. Mr. A. is certainly mistaken in his statement, made some time ago, that two or more swarms issuing at the same time through the swarmers would each return to its own hive. They won't do that in Illinois. I have used swarm-catchers for more than fifteen years, and in such cases I still use them, and they are just as good with the hivers to prevent doubling up as ever. C. H. Dibbern.

Milan, Ill.

GIVING A LAYING QUEEN TO A PARENT COLONY.

LOCATION, AND ITS BEARING ON THE QUESTION.

Question 197, found on page 928, December 1, regarding the giving of a laying queen to a colony having just cast a swarm, is a very interesting one, and one that has much to do with our honey crop if we are situated in certain localities. This whole matter of profit, resting on whether we should give such a queen or not, must be decided by our location. If the location gives a continuous yield of honey, then the giving of a laying queen immediately after swarming will prove a profitable investment; but if the location is one like the average location, which gives a good yield of honey at one or two stated periods during the season, then the giving of a laying queen at the time of swarming will generally prove decidedly unprofitable. We have been told for years that the bee-keeper who wished to secure the best results from his bees should have on hand, and give to swarming colonies, queens as above; and the reason advanced for so doing has always been, that the time lost by the parent colony in rearing a queen was equivalent to a swarm. I have experimented largely on this line; and the truth of the statement, that the time lost by the bees in rearing a queen in natural swarming is equivalent to a swarm of bees, is the first reason that it will not prove a success in locations similar to my own, which gives, at most, only two honey-yields each year. If it were bees I were after, the case would be different. With me white clover yields only enough honey to keep the bees breeding nicely, and prepares them so that they swarm mainly from June 20 to July 1. Our honey-harvest is from basswood, which blooms from July 10 to 16. Now, all who are familiar with natural swarming know that the bees are comparatively few in numbers in spring, and increase by the rapidly increasing brood produced by the queen, which, in due time, hatch into bees until a swarm is the result. By giving a laying queen to a colony immediately after it has cast a swarm, we bring about the same result (swarming) as before, for we place the bees in the same condition. The only difference is, that, having plenty of brood, they build up quicker, and are prepared to swarm in a shorter time. As this second prime swarming, brought about by giving the laying queen, comes right in our basswood-honey harvest, it cuts off the surplus honey; for it is well known that bees, having the swarming fever, do little or no work in the sections; and if allowed to swarm, the object we have sought after (section honey) is beyond our reach. If this laying queen had not been given, and we had worked so that no after-swarms had issued, we should have found that the young queen, which was to become the mother of the colony, would have hatched, as a rule, in eight days after the swarm issued, and in ten days more she would be ready to lay, which would bring the time of her laying at about the time basswood would be yielding honey nicely. During this period, between the time when the swarm issued and the young queen commences to lay, the bees, not having any brood to nurse for the last half of the time, consume but little honey; hence, as fast as the young bees emerge from the cells, they are filled with honey; for bees not having a laying queen seldom build comb in the sections. Thus, when the young queen is ready to lay she finds every available cell stored with well-ripened honey. At this point the instinct of the bees teaches them that they must have brood or they will soon cease to exist as a colony. A general rush is made for the sections; the honey from below is carried above, so as to give the queen room, and in a week we have, as a result, the sections nearly filled with honey, and later completed, if the season is not unusually unfavorable. In this way good results are obtained in such a location as this, while, if a laying queen is given, the basswood-honey season is nearly or quite used up by the colony becoming "sulky" with the swarming fever, if they can not have their own way.

After basswood we have a honey-dearth, hence the bees from the introduced queen are of no value, but, on the contrary, become useless consumers. On an average, it takes 21 days, from the time the egg is laid, to the perfect bee ready to emerge from the cell. Then, if the colony is in a normal condition, this bee does not commence labor in the field till 16 days old; hence the egg for the honey-gathering bee must be deposited in the cell 37 days before the honey-harvest ends, or else they are of no value as honey-producers. As the basswood is all gone before the eggs of the introduced queen become honey-producing bees, and as the larger part of them die of old age before buckwheat or fall flowers yield honey, a great gain is made by letting each old colony, having cast a swarm, rear their own queens, for thereby we save the expensive feeding of the larvæ, which are in turn to become expensive consumers of the honey of the hive.

These things are well worth looking into by every bee-keeper; and if brood-rearing is used advisedly, with an eye on our location, we shall find that great profit will result therefrom. The Rambler hits very close at this matter in his answer to query 197, where he says, "I want egg-laying to go on briskly when there is a prospect of those eggs hatching bees that will gather honey." In other words, if these eggs won't hatch bees that will gather honey, don't allow the eggs to be deposited. Mr. France also comes right to the point where he says, "If we should introduce a laying queen after the season was so far advanced, bees hatched from her eggs would never gather any surplus honey for us, as the season would be over before they would hatch out. I would much rather not feed brood at that time."

Reader, here is something worth carefully thinking over, for by such thinking along these lines much profit may come to you.

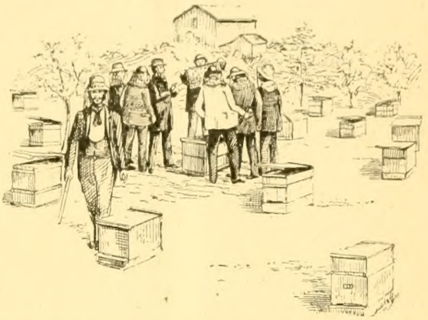
Borodino, N. Y., Dec. 17. G. M. DOOLITTLE.

[Your points, as usual, are well taken. Location, no doubt, does have a strong bearing upon the question. Right here may we suggest that this is one of the reasons why some of the large honey-producers remove their queens during the honey season?—primarily, of course, to stop swarming for the time being, and, secondarily, reduce the working force of bees at a time of year when there is no honey to be had. Bee-keepers should study well their locality. They should manage somehow to have a strong working force of the right age when they do have a honey-flow, and as light a force as possible when there is no honey to be had, and when the bees that remain are simply consumers.]

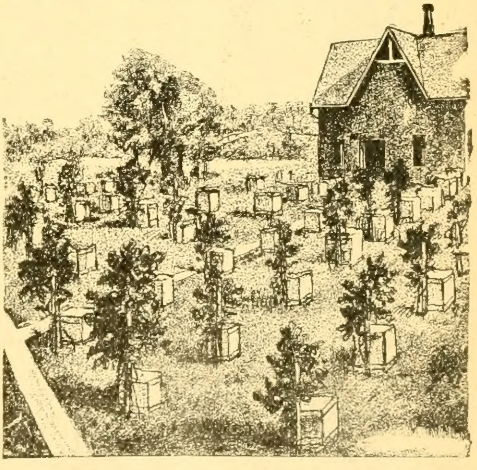
RAMBLE NO. 50.

MICHIGAN AGRICULTURAL COLLEGE.

Lansing, the capital of Michigan, is another name made familiar to a considerable class of people through the name of one man, and that is A. J. Cook, Professor of Entomology in the Agricultural College. His wide range of writings, and his valuable book on bee culture, have made his name familiar to all progressive bee-keepers. Recently calling to his aid my old-time friend J. H. Larrabee, of Vermont, the college had a sort of magnetic influence over the Rambler. We had together tramped the hills of Vermont and New York; rowed and fished for pickerel on their lakes, and can you wonder that, late one afternoon, I was in Lansing, hunting for the stage that would take me out to the College, three miles distant? At 4 o'clock the stage started from the postoffice, and, with a load of students, a keg of pickles, and some other groceries, we started. The road was excellent, but somehow the horses had a discouraged gait, and it was a relief to arrive upon the college grounds and have something else to look at. I soon found the apiary, and, anticipating that I would immediately see my friend Larrabee, I was astonished when a young man came to the door, his face lathered for a shave, and, speaking Frenchly, he was *sans skjorta;* but he evidently didn't "care a darn," and told me to sit down. When he finished his toilet he blossomed out into a good-looking young man, and I will introduce you to Fred, Bro. Larrabee's chum, studying engineering. If I remember right, he informed me that Mr. Larrabee was in the college kitchen experimenting in gastronomy. Our friend soon came in; and from his flushed appearance, his labors must have been arduous. We placed ourselves in a vis-a-vis position, and conversed on eastern themes, and particularly of the lakes and grand hills of Vermont. This portion of Michigan is a rolling country, and there are but few elevations that rise to the dignity of hills, and an Eastern traveler finds a journey monotonous; and our friend, who had been here for several months, missed his native hills. In the evening we paid our respects to Prof. Cook, who, after the arduous labors of the day, was resting in the cooling shades of the veranda.



PROF. COOK AND HIS CLASS IN APICULTURE.

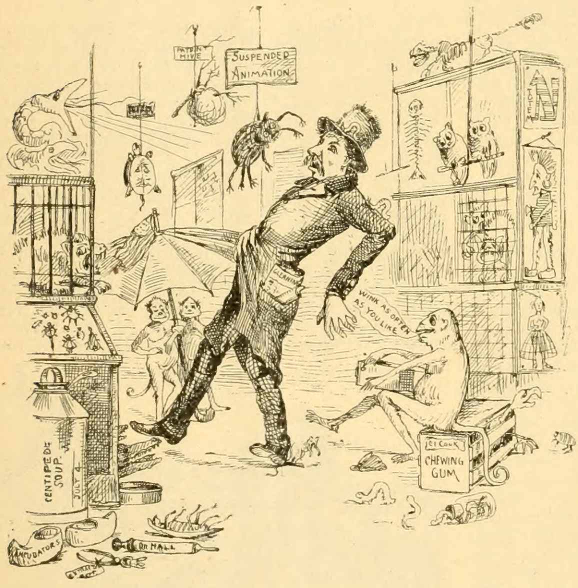


MICHIGAN AGRICULTURAL COLLEGE APIARY.

The Michigan Agricultural College was established in 1857, and is one of the oldest in the country. It has a farm of 600 acres, all under culture, and nicely located on a good stream of water. The many buildings scattered here and there among the trees remind one of those pretty summer-resort villages in Northern New York. Near the center is a campus, or playground, of several acres, where the students are put through military drill, and are taught to handle not only the musket but the big guns on the far side of the campus. Base ball and other athletic games are indulged in. It is an interesting and long journey to go through all of the departments and over the farm. I spent several days at the college, and found something new to study every day. A portion of the farm is devoted to experimental crops. In one section were a large number of varieties of wheat; in another, oats, and so with all seeds that will grow in this climate, all tested as to yield, and effect of different fertilizers, etc. Three hundred young men are here preparing themselves for future usefulness. The plan pursued is to give the theoretical or scientific education, and then put in the practical—study in the class-room, and practice in the field. In the study of entomology, for instance, when the insect *Apis mellifica* is studied in the class, a section of the class, headed by Prof. Cook, go out into the apiary, and the students manipulate the hive while Prof. Cook explains and directs. Our camera caught a very good view of the class thus occupied. Nearly all protect themselves with veils; but Prof. C. will be seen at the left in the center of the group, without a veil. Bro. Larrabee is approaching with a bold shirt-front. Many graduates of the college have taken up bee-keeping as a business; and among those who have made a stir in apicultural ranks is Frank Benton.

The college apiary contains about 80 colonies, nicely arranged on sloping ground, and shaded with grapevines. The grounds are in grass, and kept as beautiful as a lawn. The hives used are one-third Gullup, which I believe is the professor's hobby; one-third L., and one-third Heddon.

A commodious honey-house is located at one side; two rooms are devoted to the apiary. Another is Mr. Larrabee's reception-room, and in the rear is his boudoir, with a bed and a cot. Every thing in the house and apiary is kept in excellent order, and the Rambler really enjoyed the few days' sojourn. It was equal to camping on Lake George. Several experiments of a minor nature were in progress, and others will be followed up. Our friend Larrabee was just getting used to his new duties, and the fraternity should not expect too much from the first year's efforts. If bee-keepers have great problems they can not solve, send them to Bro. Larrabee, and he will give them due consideration. This place, if any in the world, can conduct careful experiments, for they have all facilities for practicing them.



RAMBLER AT THE AGRICULTURAL COLLEGE MUSEUM.

Connected with the college is a large and growing museum. In it are specimens of beasts of the field, historic and pre-historic; birds of the air; fishes, great and small; insects of all imaginable sizes, shapes, and colors; horned toads, lizards, centipedes, repulsive spiders, and, just to think of it! Prof. Cook can go into this endless menagerie and call them all pet names!

After an arduous day we sought rest with our friend in his boudoir; but that museum was too much for me, and I shall let the artist tell the nature of my dreams.

The present president of the college is Mr. O. Clute, who, a great many may be pleased to know, is the John Allen who wrote "Blessed Bees."

The glorious Fourth of July was ushered in with the distant boom of cannon. The college boys had made preparations to boom the big guns on the campus; but a lady in one of the cottages near was critically ill, and a request for quiet stilled all noisy demonstrations, showing that the young men were truly gentlemen in their deference to the sufferings of others. As there were celebrations in many towns a few miles out, the college was nearly deserted at an early hour. John H. L. said we would go to Grand Ledge, about 12 miles out, where there was to be a great celebration. On the way we would hunt up Mr. Jacob T. Timpe, the bee-man. We walked to town, secured a livery rig, and journeyed out through a monotonous country. We commented on the various phases of farm life, large farms, small houses, and no barns; we saw but few places that came up to our eastern ideas of such things. The monotony of our journey was at length relieved by coming to a considerable hill. Bro. L.'s love of home and his hills, and his glowing patriotism, got the best of him, and he was going to enjoy that hill, even if it took all day. Hurrah for the hill! The Rambler shared somewhat his enthusiasm, and, after an exhaustive time, swinging our bandanas and hats, we proceeded to Mr. Timpe's. We found him hard at work in his apiary, close beside the road. Said he to Bro. L., whom he had previously met, "Is that the Rambler feller you have with you?"

Mr. T. had his yard full of hives and nuclei, and was raising queens at a high-pressure rate. We first had the impression that the hives were arranged by driving a load into the yard and letting them drop out at the rear, as we once read in Gleanings; but Mr. T. didn't do that way. A cyclone must have picked up a hive here and there in various States, with a few board fences and chicken-coops, and landed them all in Mr. T.'s yard. But Mr. T. had a new yard in mind, and no doubt he now has one equal to the college apiary. He handled his bees without smoke or veil, and seemed to be proof against stings. Mr. T.'s were of the five-banded order, and his method of rearing a combination affair. Strips of drone comb were cut *a la* Alley, larvæ inserted *a la* Doolittle, and the strip pinned on the side of a comb *a la* Timpe. We were shown several very fine queens. Mr. T. is a young man, and evidently cut out for a progressive bee-keeper.

We went to Grand Ledge to celebrate; found the little town full of people celebrating on a roller toboggan slide, and rowing around in a sort of duck-pond. The Grand Ledge from which the town received its name was about 50 feet high. We soon tired of this tame celebration, and returned to Lansing via another route. I dare not trust my friend near that hill again.

The gossip around the campus the next day was about the episodes of the Fourth. Fred had won a prize in a foot-race; another student was in a fight; another came back the worse from beer. So the Fourth passed into history, and on his journey again passes the

RAMBLER.

[The Michigan Agricultural College is a grand place to visit. It is an institution that the State of Michigan may well be proud of. By no means the least important personage of the college is Prof. Cook. In fact, he is more widely known for his researches and writings than any other instructor or professor in the college.]

BOUNTY ON HONEY.

A GOVERNMENT STAMP ON HONEY, AND WHY.

The meeting of the Illinois State Bee-keepers' Society at Springfield, on the 16th and 17th, was pretty well attended, especially by bee-keepers near Springfield. I was quite sorry not to see Messrs. Miller, Dadant, and Newman present. Still, I believe that considerable good has been accomplished. The proposition of the Northwestern was gladly received, and the request to meet in Chicago once each year was unanimously acceded to. There, now, brother bee-keepers, not only of the northern part of the State of Illinois, but all of you in reach of Chicago, come and help us make the Illinois State Bee-keepers' Association what it ought to be. Our interests are one and the same, and we ought to see to it that the annual appropriation is well expended. This society ought to take hold of the World's Fair business. Of course, I don't think that it ought to try to monopolize the honey and supply exhibit, but it ought to have a committee there, at least, to welcome the bee-keepers from other States and from all over the world.

There is one thing that I think ought to be agitated everywhere, and as often as possible; and that is the two-cent bounty on extracted honey. The comb-honey production doesn't need it. Now, were the bounty the only thing in it I don't know that I should think it so important. But, here: let the government go to placing a stamp on what honey is actually produced here in this country, and the adulteration of extracted honey is at an end. See what the government does for the liquor interest. It not only labels and stamps their different brands, but places a penalty on using their packages a second time. If we can only get this bounty on extracted honey it will do more to lift up the bee-business and encourage the bee-keepers than any thing else I know of, for it will soon make an almost unlimited market for extracted honey, for every one will then have confidence in the purity of what he is purchasing, for then there will be the government's guarantee as to its purity on every package. What more could any purchaser ask for? Besides this, there is no doubt that the darker grades of honey have got to come in direct competition with sugar that does get a bounty from the government. Now, why should the sugar interests have an advantage of over 25 per cent on their output, and the honey interests be forced to compete with them for a market? Such a condition of affairs is manifestly unjust, to say nothing of being forced to compete with a mixture of glucose. The government would, in this way, take the very best census of the bee-keeping interest that it would be possible for us to have.

I had the pleasure of visiting the Lincoln Monument in company with Mrs. Harrison, while at Springfield. She agreed with me that, if we could get this government stamp on extracted honey, it would be of immense advantage to bee-keepers. She seemed to think, also, that the bee-business is becoming rather risky, with the present prices for honey, and the fact that the bee-pasturage is year by year becoming poorer and poorer since the amount of land that is not tilled is becoming less and less. Low wet places, that were formerly too wet to be cultivated, were the natural home of plants producing honey, but they are now either being ditched out or else underdrained. At Peoria, where her bees used to get an abundant harvest, it is now occupied by a thriving city.

FURNISHING REPORTERS MATTER RELATING TO CONVENTIONS.

In returning home, a reporter who had seen me in the meeting came and sat down by me, and began to make inquiries about bees and honey, and about the association. He went on to say that they would have been glad to give the bee-keepers two or three columns of matter in their journal, while there at Springfield, if they had had any way of getting the copy. I wonder if we can't get the conventions to take the hint, and have a committee to prepare copy for the reporters when they come around—have it ready for them. In this way a large part of the public can be reached and educated in regard to honey and bees that can not be reached so easily in any other way. Instead of growling at what daily and weekly newspapers publish, try giving them facts, in a readable shape, to publish. A. N. DRAPER.

Upper Alton, Ill., Dec. 19.

[We believe this is an important question, but it is one on which we are not yet prepared to give an opinion. We hope it will be thoroughly discussed in the next few weeks, both as to the desirability and feasibility of having a bounty on honey. Mr. Elwood touches on this same point in his president's address, which we will publish in our next issue.]

BEES OF ITALY, AGAIN.

ITALIANS A FIXED RACE; AMERICANS TRYING TO IMPROVE THEM.

I noticed a communication by Arthur T. Goldsborough, on page 842, 1891, in which he asserts that the bees of Italy are not three-banded. I was in hopes some of the older writers would give us a chapter on the color of the Italian bee; but so far I have not seen such a communication. It seems strange that this writer, being as close an observer as he claims to be, should assert that no bee would show more than one yellow band. Now, the fact is, among all classes of bees, all mixtures and crosses, I have never been able to find a single bee with only *one* yellow band. Wherever I find a bee with yellow on any bands, there is yellow on the three; and, again, if the bees of Italy are not three-banded, how comes it that, of all the bees that are yearly imported from there, no importer has received a single bee that does not show the three yellow bands? Any importer will guarantee this. Another thing, all the queens that are brought from Italy are not tested queens. Especially last spring, the breeders of Italy could not fill all their early orders with tested queens, and get them here as soon as the importers wanted them; and yet the bees of Italy, so far as I have seen them (and I have received queens from several breeders in various parts of Italy), are three-banded. The bands are not bright yellow, but more inclined to be red; and I believe *the darker colored these bands are, the better workers the bees prove to be.*

I notice, both by the circulars of breeders and by several letters which I have, that the first thing the average American tries to do is to improve the Italian bee. This is a characteristic of the American, and "improvement" is his motto; but how is a person to undertake to improve a thing that already has fixed characteristics? I find that this "improvement" (?) consists in making it yellow, *yellower*, YELLOWEST.

While I have no objection whatever to these yellow bees, and have and intend to continue to keep the yellowest bees procurable, yet I will say for them that they will not reproduce themselves. Out of ten queens from a five-banded mother, mated in an apiary where drones from five-banded mothers abound, not more than two of the untested queens will prove to be five-banded. I find the five-banded bees as gentle as the imported stock; but the bees from queens of five-banded stock that produce bees with only three bands *are not gentle.*

Last season there were many of these queens sold. Last fall at the fairs I found many disappointed purchasers of them. They had bought untested queens of them, expecting to get some five-banded. They had failed, and consequently they were disappointed.

The Americans have bred the short-horn until he is a fac-simile of the Devon. They have bred the Poland-China until a whole field full of experts can not tell a Poland-China from a Berkshire, ears alone excepted. And they have bred the Italian bee until it is identical with the Cyprian. Now, this has not all been done by "judicious selection."

When there is a demand for any type of animal or bee, the Americans are going to supply that demand, and do it right speedily.

Why is it, Mr. Editor, knowing as you do the nature of the imported bees to produce workers almost identically the same, you charge about double for a queen from an imported mother, that herself happens to be a little yellower than ordinary? W. C. FRAZIER.

Atlantic, Ia., Dec. 16.

[Our experience as importers is quite in line with yours. Next to the Italian bee-keepers themselves, the importers who receive annually large consignments of queens from that country ought to be in position to judge of the general characteristics of the bees. It is our experience that imported Italians are as fixed as any race of bees known, in their general characteristics, with the possible exception of the black, or German race. Of the hundreds of queens we have imported from Italy, we never saw any four or five banded progeny from any of them; neither have we seen any one-banded progeny. They have been uniformly three-banded bees, though in the progeny of a few the third band was quite indistinct, and some would pronounce them only two-banded. It is remarkable that the bees of Italy should show so generally such fixed qualities, and that these qualities should duplicate themselves so nearly in the first generation. It is a fact, as we have often repeated, the bands of the importeds are leather-colored, or, at least, a dark yellow; and these darker bees have so far given better results in honey. We therefore take the liberty of putting in italics what you say on this point.

It is true, that Americans will endeavor to give people what they want; and because there is a demand for yellow queens, and because of the fact that only a few of them are among the daughters of imported mothers, we have had to charge more for them; but as we say in our price list, their bees will have no more than three yellow bands, nor will they be any better honey-gatherers than those from darker daughters. In regard to the article of Mr. Goldsborough, you will see, by turning to page 948, Dec. 15, that he must have visited only a few localities in Italy, or else he observed very carelessly. Although not intending to misrepresent, his article gave a very incorrect idea of the kind of bees found in Italy.]

THE HUBBARD BEE-HIVE.

ITS MERITS SET FORTH.

Friend Root:—As brood-frames with fixed distances have attracted so much attention of late, I think it possible you will be interested with a description of the Hubbard hive, which in a measure combines both fixed and movable distances. It was patented Jan. 16, 1883. The main objects attained by having my brood-frames hung in this way are:

1. They can be swung out to the left, giving plenty of space in which to remove combs without danger of scraping them together.

2. They are spaced 1½ inches from center to center, at the front end, and at the rear end of the frames a long staple sets in fine, deep, saw-tooth notches which allow the frames to have their distances varied, and at the same time stay where they are put, as the frames will not move unless the hive is turned on its side. The adjustment at the rear end allows a queen-cage to be introduced, or the distance to be varied to accommodate combs of different thickness.

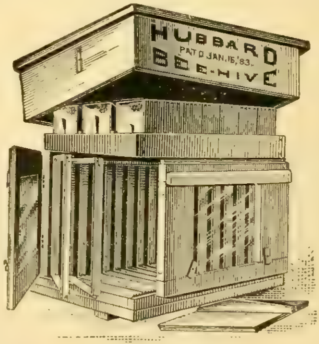
3. Each end of the frame has a projecting nail at the upper left-hand corner and a long shallow staple below; therefore the frames may be hung either end front.

4. Frame-bearings are metal, and, being, small, do not get waxed fast.

5. This accomplishes the fixed-distance idea without danger of crushing bees between wide end-bars or top-bars, and with no projecting top-bars to catch them.

6. The staples in the bottom of the frames keep bees from being crushed under the bottom-bar when you set a frame to one side on a flat surface.

7. When returning a frame to the hive you find it practically self-adjusting. Get it somewhere near its place, and large notches in its tin bearings at the front end guide it instantly to its place, while you swing it to the point at which you wish it at the rear.



8. Hives ought always to slant a little toward the entrance. This hive does; and by having a frame—hanging below at the front end, a bee-passage is always maintained; the frame does not sag and get waxed fast, nor make a harboring-place for vermin.

9. The apiarist does not break his back looking over his brood-combs. Several years ago, when our friend Hutchinson was in the queen-business, he gave us a description of the backache from handling bees that many will remember. Well, with this side-opening hive you drop down on one knee, sit on your heel, and handle your bees with an ease you would hardly believe possible. As to finding queens, it is usually done without removing the frames from their front hangings; swing them around and look down between them.

Are these points honestly taken? Come and see for yourself. Seven miles from the city is Albert H. Grover's Hubbard-hive apiary of from 125 to 150 colonies. This is where my bees and queens are raised. Any man within, say, 300 miles of here, who will ship 50 colonies of Italian bees to this apiary in any other hive, and find all the queens as quickly and easily as Mr. Grover will from 50 of his colonies of equal strength, will have his moving expenses paid, and good wages for his time. Is the hive expensive? No more than other single-walled hives. Is it complicated? Many practical bee-keepers, after seeing the hive itself, say it is much more simple than they expected after reading printed description. A break-joint honey-board is used between brood-chamber and super. Several thousand of the hives are in use in over twenty States. G. K. HUBBARD.

Fort Wayne, Ind., Dec. 12.

[As the question of fixed distances and the finding of the queen by *not* removing the frames has of late been agitated, we asked Mr. Hubbard to give us some of his experience along this line, in connection with his hive. We have no doubt that he can, many times, find the queen without removing a frame; but for some reason or other, side-opening hives have never been popular with the masses of bee-keepers.]

THE IMPORTANCE OF SEPARATORS.

SHALL WOODEN SEPARATORS BE THICK OR THIN? THE SERIOUS INCONVENIENCE AND COST IN HAVING THEM WET WHEN PUT IN SECTION-CASES.

I have always had quite an opinion as to the importance of separators, and latterly I have raised my opinion as to their importance. A good many imperfect sections I have traced to imperfect separators. That is, if a section is nearly finished, and then is moved to some other part of the super where the separator is not exactly like the one where it had been, then wherever the separator comes a little too close to the section the comb is likely to be gnawed away, and little bridges of wax built from the comb to the separator. I have seen a section, one side of which was entirely finished, have its finished side nearly all unsealed just because, when moved, the space between comb and separator was not as great as it had been in its first position. And although I am not sure of it, I think there have been cases where the warping of a separator made trouble with a section, although its position had never been changed.

I think it is pretty generally agreed that wood is better than tin for loose separators; and as a large proportion of separators used are loose, it becomes an important matter to know just what is the best wood separator. I have seen separators a quarter of an inch thick, and it always seemed to me like a waste of lumber and super room. Still, I never used any of that thickness, and it is possible that they may have advantages of which I do not know. When wood came to be largely used for separators, and they consequently came down to a very moderate price, I decided that the labor of cleaning them of propolis after being used was worth more than the cost of new separators. So for several years I have used for kindling-wood most of my old separators.

Then the question arose: If they are to be used but once, is it not worth while to try very thin separators? So I have tried different thicknesses, from $\frac{1}{30}$ of an inch to $\frac{1}{16}$ or thicker. The very thin ones seemed to me more desirable because they would take up less room, make a little less chance for propolis in cracks, and especially because they were tougher. For it seems to be true that a very thin separator will be sliced off without breaking the grain of the wood as much as it is broken in one twice as thick. But upon trial I did not find the very thin separators desirable. Sometimes the bees would gnaw away a considerable portion of one edge, and sometimes the separator would curl, as it appeared to me, solely because it was so thin. On the whole, $\frac{1}{16}$ may be the best.

A knot in the wood, no matter how small, is fatal to its fitness for a good separator. Sometimes a separator will be curled a quarter or half inch out of true where no knot can be seen; but the grain of the wood shows that it was in the neighborhood of a knot, and for some distance from a knot the grain is generally twisted enough to allow considerable warping in a very thin piece.

I don't know what is the best wood, but I am inclined to the belief that poplar or whitewood is not so likely to curl as linden. It is possible, however, that more knots were allowed in the linden that I tried than in the poplar.

I once got a lot of separators that were not thoroughly seasoned. In fact, they were quite wet. You would hardly believe the damage those separators were to me. Being wet, they were too wide, so that I could not put in the little ¼-inch separators on top; and the curling! and the twisting! In some cases, in spite of their being pressed between the sections, they bent over fully half an inch out of place. And if a section had its place changed, or if a number of unfinished ones were put together in a super to be finished up, then there was fun. Many a one of those sections came out of the super more unfinished than when it went in. If I ever get any more wet separators I'll put them in the fire to dry, and I'll let them stay there till they've dried into ashes.

What should be the length of separators? I'm not sure about it, but I think about an eighth of an inch shorter than the inside of the super. That's the length I've used them, but possibly I might like better to have them only a sixteenth shorter. If the least bit longer than the space they are to fill, they are very troublesome to get in, and can be got in only by a bend somewhere in their length. If too short, one end gets inside of a section, and then the trouble is still worse.

A further trial, during the past season, in all my supers, of the little separators on top, confirms me in my liking for them. Although I had forgotten about it, I first saw them used by B. Taylor. My supers are 17⅜ inches long inside, and four 4¼ sections take up 17 inches of that, leaving a ⅜-inch play at top, for the T tins take up the play at bottom. Now, that ⅜ at the top is entirely too convenient a place for bees to fill with propolis, and I want it *entirely* filled with something else. Three separators, each ¼x⅛, just exactly fill it. I supposed the fit would be so tight that it would be almost impossible to force these little separators into place; but in actual practice I find no great difficulty. Besides keeping out glue, they are useful in keeping sections perfectly square. I had a box of sections that made up so much out of square that I set them aside and stopped making them. Many of them were so much out of square that, when put in the super, one corner of the section stood up a quarter of an inch or more higher than it ought. If pushed down into place, they would immediately spring up again. But with the little separators I found I could use those same sections. They were squeezed so tight that, when pressed down into place, they were held there. I heartily commend these little separators to every one who uses the T super. C. C. MILLER.

Marengo, Ill., Dec. 15.

[Your experience seems to be quite in line with our orders. The call has been for separators, as a general thing, not thinner than $\frac{1}{16}$ of an inch. Some have called for even thicker ones. When sliced up, the grain is more or less broken. It would be desirable if we could saw them and yet not have them expensive.]

FEEDING BEES CANDY FOR WINTER.

A. N. DRAPER GOES THROUGH A LITTLE EXPERIENCE.

On page 9 of "Advanced Bee Culture," Mr. Hutchinson says: "If by any hook or crook the bees have gone into winter quarters short of stores, and there are fears that some may be starving, it is better that they be examined and fed if needed, even though the task is unpleasant. There need be no hesitancy in thus disturbing the bees for fear that it may do them some injury, for, as a rule, it will not. If some colonies must be fed, and no honey is available, the best substitute for honey is candy made of granulated sugar, put in sufficient water to dissolve the sugar; then boil the syrup until it will harden in cooling. Watch it carefully and try it frequently. As soon as it is sufficiently hard, remove it from the stove and pour it into shallow dishes to cool. Be careful not to get it too hard."

On page 154 of "Bees and Honey," Mr. Newman says: "For winter feeding, use four parts coffee A sugar and one part water; simmer until it becomes quite hard on being cooled; mold into frames of one inch in thickness, and lay it on top the frames, using sticks underneath, one-half inch square; or mold into brood-frames; tie hemp twine around to hold it in place, and put it in the center of the brood-chamber."

There, I tried to do it! but I suppose that both my A B C book and Langstroth Revised have been loaned, or else sold, as neither one of them could be found. It was real cold, and an out-apiary of about 70 hives, in which I have only a half-interest, and which is about eight miles away, was found to be almost destitute of stores. As I had been badly crowded all the fall with my business, I had left the care of this apiary to Mr. Dorsey, and he probably overestimated the amount of stores that these hives contained. None of them had been moved to the lake, and had had the honey-dew taken off in August. They are in eight-frame Simplicity hives, consequently too much of what they had on hand in August was taken away from them. Well, I made up my mind that the best way that these bees could be fed would be with "candy." How can I manage to get enough shallow vessels to hold a barrel of syrup? After thinking a while I concluded that No. 5 butter-trays were what I needed, so I sent down for a crate containing 250 of them. It cost me 75 cents. I have a large stove-kettle, capable of holding 30 gallons. I use a tin can inside of this kettle for liquefying candied honey. If the syrup is made inside of the can with water around it there would be no danger of getting the candy scorched. If scorched, it would be worthless for winter feed. But then, if I get it too thin it would be a slow job to cook it down, in this manner. As it had been thoroughly cooked in making the sugar, what good would it be to put a lot of water in it to boil out again?

I made the candy in this way: I first weighed 25 lbs. of water and placed in the can. When it got boiling hot I weighed 25 lbs. of granulated sugar, poured into the water, stirred it until it dissolved, then poured in 25 lbs. more sugar, and stirred until it dissolved. One hundred pounds of sugar will all dissolve; but in order to get it to harden so that it will harden sufficiently to haul to an out-apiary it is necessary to put in from 15 to 20 lbs. more of sugar. Now, it is necessary to place the butter-trays on the floor, or on shelves with a small stick under each side of the trays, to prevent them from turning over when filling, and while the candy is hardening. The trays hold about 2 lbs. of candy each. I fixed up nearly a barrel in this way, and took it out and placed it on top of 51 hives. The following card, received from Mr. Dorsey, will explain matters.

Dear Honey:—Your candy is going fast. It is dry and hard, and all gone back to sugar. I think they are carrying most of it outside. Better come out right away before it is all wasted. DORSEY.

Moro, Ill., Dec. 11.

There! A. N. DRAPER.

Upper Alton, Ill., Dec. 15.

[Now, look here, friend D. You led us to believe you were going to make a grand success of your venture; and just at the point when our expectations were raised to the highest notch, you turn the tables by quoting a card from your neighbor Dorsey. As Josh Billings said, "Eggsperiens teeches a good skule, but the tuishun comes purty hi." Joking aside, as nearly as we can make out you did not follow directions carefully. Your candy was too hard. Notice the last clause from your quotation from Hutchinson. In order to be suitable for the bees there should be enough water incorporated in it to make it tolerably soft, and yet hard enough to hold its own. We have made candy, and poured it on butter-dishes, as you say, and it worked beautifully. It might not have been a bad idea for you to have tried a little at first, before melting up the whole batch. We have had some experience ourselves; and if you were to turn to the subject of Candy in the A B C book you would find this: "Perhaps you had better try a pound or two first, while you get your hand in. Our first experiment was with fifty pounds. It all got 'scorched' 'somehow.'" You might have used Good (or rather Scholz) candy and been perfectly safe.]

MELILOT.

SOME INTERESTING EXPERIMENTS FROM H. R. BOARDMAN.

Dr. C. C. Miller sends a letter which he has received from H. R. Boardman, and suggests, as it comes from such a source, and as it seems to be so well worthy of publication, that we give it insertion in our columns. This we are very glad to do; and if friend Boardman has any further facts we should be much pleased to hear from him again, more in detail. We are very sure he will have no objection to being lugged into print in this way.

Dr. Miller:—You may remember that, at the Columbus convention, I expressed a good deal of confidence in regard to the value of sweet clover as a forage-plant for stock. There was considerable discussion on the subject. If I remember rightly you were among those who sympathized with my own views. The proof of the pudding, you know, is in eating. I am collecting some of this same kind of proof in regard to sweet clover. I am now feeding it to my cow once a day. She seems to eat with a relish all that I give her, to the least and last leaf and stalk. This clover was of the first year's growth from the seed, and grew thick and fine, and was cured in good condition late in the season. I feed it to my horses. They eat it, but I think it is better for cattle and sheep. A farmer living near me, with whom I am well acquainted, has a strip of sweet clover growing along one side of a lot next to the railroad, where it spread from the railroad embankment. He pastured a flock of sheep in this lot last summer, and he said to me those sheep persisted in eating this clover when the feed was abundant elsewhere in the lot. He supposed nothing would eat it; but they did, and kept it fed down close. They seemed to prefer it. He did not know why. He regarded it as a nuisance, notwithstanding the evidence he gave in its favor. He is not a bee-man. So much for a bad reputation.

I have seven acres, sown last year. It will bloom next season. I am sure it can be raised on our hard clay land, and made profitable.

H. R. BOARDMAN.

East Townsend, O., Dec. 1.

THE NORTH AMERICAN CONVENTION AT ALBANY.

REPORTED BY ERNEST.

The Albany convention has come and gone, and only memory remains to recall the feast of good things. It was indeed a representative convention, perhaps more States being represented, and more miles traveled by bee-keepers, than to any other convention in the history of the association. Something over 100 railroad fares were paid to Albany, and many of these fares covered long distances. As was expected, there was a large number of distinguished bee-keepers present, although not all that we hoped would be. A. E. Manum and Mr. Frank Benton were detained on account of sickness, as were also the two doctors, Mason and Miller, much to the regret of all present. The doctors are a whole team in themselves, and are enough to make any meeting bubble over with enthusiasm. But we had other good men. Capt. J. E. Hetherington, the one bee-keeper who enjoys the distinction of being the largest honey-producer in the world, was present. He is full of vim and business push, it was easy to see. A delightful and interesting speaker, he fairly captivated the whole convention by his joviality and enthusiasm. G. M. Doolittle was another bright light. I had always supposed that he was more of a writer than a convention man; but I was very agreeably surprised. Like Mr. Hetherington, he is a clear and forceful speaker. C. P. Dadant and Hon. J. M. Hambaugh came from the Mississippi Valley, and Eugene Secor came from beyond the Mississippi River. They had come the furthest of any of the bee-keepers. Of these I'll tell you more in our next issue. There were also two representatives from Canada, in the persons of R. F. Holtermann and R. McKnight. I believe nearly every one of the New England States had one or more representatives. The New Hampshire Experiment Station actually sent one of its instructors, a Mr. Wood, to the convention, the ultimate object being to establish a school of apiculture. Of course, the York State bee-keepers turned out *en masse*, among them being J. H. Nellis, of the former *Bee-keepers' Exchange*; Julius Hoffman, P. H. Elwood, G. H. Knickerbocker, N. D. West, W. E. Clark (he's quite a driver in convention), Thomas Pierce, the two Coggshalls, I. Schofield — I guess I'd better stop, or somebody will feel hurt because I didn't mention his name.

This convention, while it lacked some of the enthusiasm of other meetings of the association, was remarkable in that there was not a word of discord uttered. The pleasantest and best of feeling prevailed at every session. With Drs. Mason and Miller, supported by Capt. Hetherington and Doolittle and the rest, the enthusiasm would have run high. As it was, it did not go down to a very low ebb.

Were there any women-folks present? Only one or two at a time, and that, too, after all I had said about bringing along the wives, sweethearts, and daughters! I'm not discouraged. I'll invite 'em to come to Washington next year, and they'll come.

Well, what about the convention? What did they say and do? More things than I have space to tell you. A very full report by that prince of reporters, W. Z. Hutchinson, will appear in the *American Bee Journal;* and if you are not already a subscriber of that journal, send 10 cents for a few sample copies, and you will be amply repaid. I will attempt to give you only a gist of the subjects discussed. The president's address is so excellent and important in its suggestions that we have decided to publish it entire in our next issue.

INCORPORATION, AND WHAT IT MEANS.

The North American is now incorporated under the laws of the State of Illinois. At the first session it was asked what incorporation meant, and why any particular State should take jurisdiction. It was explained that incorporation signified the making of the society into a legal body, and, so to speak, an individual capable of transacting business—one that can sue and be sued. As to localizing the incorporation, it was explained that a society, in order to be incorporated in the United States, has to come under the jurisdiction of some particular State; and as Illinois is centrally located, as far as the Northern bee-keepers are concerned, Chicago was thought to be an appropriate place for its headquarters. All other societies that are incorporated, whether fraternal or otherwise, are under the laws of some particular State, though in their practical workings they may be national. The North American had also procured medals, as per the clause in its constitution, and was ready to distribute them to affiliated societies when called for.

BEES, THE LOCATION, AND THE MAN.

Mr. Doolittle gave us an excellent talk on the subject above. The first thing of prime importance is the queen. We should not have excessive brood-rearing after the honey-season, but encourage it by all possible means *before*, so as to have a force of bees of honey-gathering age come on at the right time. As to location, most of us, Mr. Doolittle said, are bound by our environments, and therefore the location may be good or bad; but all honor to the man who secures good crops in a poor location. As to the man, he must be one of push—one not working to fill out so many hours, but working for a certain definite result. He must enjoy his work;

and the bee-keeper who has made a success must be an enthusiast.

BEES BETTER THAN FARMING; CAN BEE-KEEPING BE MADE A SPECIALTY?

A lively discussion followed after Mr. Doolittle sat down. It assumed all sorts of phases. For instance, "Do bees pay better than farming?" The reply was made that it did. As to whether it paid to make the bees a specialty, or mix in other things, was also discussed in a lively manner. While the majority evidently seemed to think it did pay, a few insisted that it did not. Capt. Hetherington was not sure whether he was a specialist or not. When a boy sixteen years old he wrote to Mr. Quinby, asking whether he had better make bees a specialty. Mr. Q. advised him not to do so, and suggested connecting it with dairying or school-teaching. The captain asked us to note how very few of the old bee-keepers who had made bee-keeping a specialty had made it a success. Mr. Doolittle was then asked the question as to whether he was a specialist or not. He was hardly prepared to say that he was. His main business now was queen-rearing, while, years ago, he produced comb honey. Why didn't he do so now? some one asked. Because, years ago, he got 28 cents a pound, and now it has come down to 12 and 15. While queen-rearing paid him, he also thought the production of honey would pay, even now. The feeling seemed to prevail that it is not wise to embark in bee-keeping hastily as a specialty. If you have already something that pays you well, don't dabble in bees.

CONTROLLING SWARMING.

A paper from W. F. Clarke was read, on the prevention of swarming. By knowing the cause we may bring about a cure. He asked, "Are not our hives too small, or overcrowded?" and added, "Is not swarming a great deal like emigration?" He believed in plenty of room, and in keeping the hives in a shady place.

Quite a discussion followed the reading of this paper. Most of those present seemed to acknowledge their inability to control swarming, and some others averred that they did not care to do so—it is nature, and nature should be gratified, because more honey is secured thereby. It was easy enough to control swarming when running for *extracted* honey, by the use of perforated zinc: but when it comes to the production of comb honey, it was another matter. The question then came up as to controlling swarming by caging or removing the queens, as is practiced by Elwood, Hetherington, and A. E. Manum. G. M. Doolittle and J. E. Crane could not make it work. President Elwood was then called upon. Some varieties of bees, he said, are much more inclined to swarm than others. They ran about 900 colonies for comb honey, and there was not one strong colony out of all that number that did not attempt to swarm. Half of this number they subsequently reduced in strength, and from the other half they removed the queens. From the latter they got more honey. Mr. West succeeded in controlling the desire to a very great extent by the use of his queen-cell protectors—that is, he would destroy all old queens just before the swarming season, and insert cells from choice queens in his protectors in the colonies made queenless. When the young queens got to laying, the swarming fever would be over.

THE ITALIAN BEE, AND HOW SHALL IT BE MARKED?

Mr. Knickerbocker read an essay on the Italian bee, showing the principal points of excellence. Italians, he said, work earlier and later, and breed up earlier, and store honey in the brood-nest. As to which quality we should give the preference, that depended upon circumstances. If we want bright colors, breed for them; if we want honey, breed for honey and good wintering qualities, rather than for bright colors or particular markings. But Italians have certain general characteristics and markings; and it would be very desirable to have a standard that the National Association could agree upon. It is now an undisputed fact, he said, that many Italians have been sent out that were mixed with Cyprian blood. Italians must be Italians, and nothing else.

A lively discussion followed the reading of this paper. Many took the ground that a standard could not be made; and the point came up as to whether the Italians are a pure race of bees or hybrids. The discussion grew "redhot," as the boy said; but every one "kept sweet." Doolittle averred that the Italians were hybrid, because they were so much inclined to sport, and that the black bee was the only pure race. Dadant and one or two others insisted that the black bee was not a pure bee—that there were varieties or sports of this race. The discussion waxed warm until a committee was appointed by the chair to follow out Mr. Knickerbocker's suggestions—that is, draw up a standard with a scale of markings for recommendation to the convention. This committee was composed of G. H. Knickerbocker, G. M. Doolittle, C. P. Dadant, and J. E. Crane. When the committee assembled, the old bone of contention was renewed, and they took sides, neither party being willing to yield to the other. I longed for a Kodak, or something to photograph them. It was a real sight to see them argue with their index fingers pointed toward each other. They finally compromised matters very nicely, and the report, with one or two amendments as adopted by the convention, is as follows:

WHAT CONSTITUTES AN ITALIAN BEE?

Italian bees must adhere to the combs when properly handled, and not cluster about, or rush around and fall to the ground. They must have three bands, of a color ranging from golden yellow to leather color. They must be quiet when well handled, and in time of scarcity must place their honey in a compact shape.

SCHEDULE OF MARKING.

Comb-building, 10.	Wintering, 15.
Honey-gathering, 35.	Gentleness, 10.
Prolificness, 15.	Color, 5.

APICULTURE AT THE COLUMBIAN EXPOSITION.

A paper was read by Dr. Mason, on the outlook of apiculture at the Columbian Exposition. From it we learned that all exhibitors are to be on the ground by April 1, 1893, and that each State, for its honey-exhibit, would be allowed only 100 square feet. Colorado bee-keepers alone had applied for 1000 square feet. This was a poser. In the discussion which followed, it was urged that we ask for more space, as 100 square feet per State would be insufficient. But over against this it was urged that all the States would not attempt to make an exhibit of honey, and their apportionment of space would go to help make up the allotment of the States that did wish to exhibit. During the course of the discussion, Capt. Hetherington, who has had much experience, told us, in a very interesting way, of the honey-exhibit which he prepared for the Centennial in 1876—an exhibit which attracted so general attention at the time. He gave us many interesting suggestions—suggestions which the committee will probably make use of. A committee of three, consisting of Dr. Mason, P. H. Elwood, and Hon. J. M. Hambaugh, with Dr. Mason as chairman, was appointed to confer with the proper authorities of the exposition at Chicago, with reference to an apiarian exhibit at the World's Fair. As heretofore, the convention was about to recommend Dr. A. B. Mason as the right man to take charge of the honey-exhibit. Some one, I believe it was Mr. Dadant, said it was an unnecessary step, as the commissioners would follow their own sweet will, no matter what recommendation we might make. In the general discussion it was regarded that this was the golden opportunity now before the bee-keepers of the United States to make a grand exhibit—one that would be educational, and of much importance to the industry. It was not an opportunity that we could afford to let slip by, and it was hoped that the committee appointed would give the matter the attention it deserved.

SPRAYING FRUIT-TREES AND POISONING BEES.

At one of the sessions Prof. Somebody (I have lost the memorandum of his name), of the Department of Entomology of the State of New York, was introduced to the convention. The professor desired to ascertain to what extent bee-keepers had experienced trouble from the poisoning of their bees as the result of arsenical sprayings of trees during fruit-bloom. He had always urged, in his advice to fruit-growers, to spray the trees just before and just after blossoming, but he said it would be a great advantage if they could, without detriment to the bee-keeper's interests, spray *during* fruit-bloom. It was his opinion that the arsenical poisons were so weak that they would do no harm to the bees, even if the blossoms were sprayed during full bloom. As this was a convention of representative bee-keepers from all over the land, he desired expert testimony, and sat down.

Very promptly C. P. Dadant, supported by Hon. J. M. Hambaugh, told of an instance of a neighbor's bees that had been poisoned by the thousands—in fact, the apiary was almost exterminated by the spraying of fruit-trees during the time of blossoming. The professor seemed hardly satisfied with this and wished better proof. He desired to know whether a chemist had made an analysis of the contents of the honey-sacs. The gentlemen replied that the chemist had not done so, as they regarded the proof sufficient. The professor would not regard this as a *scientific* proof. The bees, he thought, might have died from other causes. But Dadant and Hambaugh insisted that it was significant that the bees died just at the time of spraying; and when the spraying had stopped, the dying-off of the bees stopped also. Still the professor was a doubting Thomas. The Hon. J. M. Hambaugh said he introduced the bill in his own State, Illinois, for forbidding the spraying of fruit-trees during the time blossoms were on, and the bill had nearly passed. He was urged to draw up this bill by a pressure of bee-keepers from all over that State, who had complained of poisoning from the sprayings. About this time expert testimony began to pour in from all parts of the convention. J. E. Crane, of Vermont, and somebody else, testified that they had actually seen bees dead and dying under trees that had been sprayed with arsenical poisons; and the doses for the spraying were no stronger than was recommended. I was myself surprised at the number who had seen bees poisoned from the spraying of fruit. If a multitude of testimonies and a strong array of circumstantial evidence mean any thing, the professor must undoubtedly have been convinced, even barring the chemical analysis of the bees' stomachs. At any rate, he seemed satisfied, and said he would continue to advise as he had done heretofore, to spray before and after blossoming. A vote of thanks was then tendered him for his kind consideration in our behalf.

One of the valuable services that this convention has rendered is to have the bad results of spraying during fruit-bloom. It also showed that the interests of the fruit-grower and honey-raiser are one; that all the results that can be desired can be accomplished after the petals have fallen off from the miniature fruit. Prof. Cook's able paper, read before the Association for the advancement of Agricultural Science, at Washington, and published on page 732, 1891, was introduced in evidence.

TWO SIZES OF SECTIONS FOR A STANDARD.

An essay was read from Dr. C. C. Miller, on the subject as above. The doctor discussed the desirability and feasibility of having two sizes as standard. They necessarily cost the supply-dealer more, and therefore indirectly the bee-keeper. It would be desirable, he thought, to have only one standard; but in the present condition of things, that seemed impossible. He rather objected to 1⅞ sections for one of the standards, because they hold less than a pound, and because the consumer buys it for an ostensible pound package, when it was not. He did not wish to be a party in any such business. In connection with the essay were read two letters, one from W. T. Falconer, and the other from the G. B. Lewis Manufacturing Co. Both held the ground that it was desirable to have a standard if it could be adopted. The 1⅞x4¼x4¼ comes as near as any thing to being a standard; but besides these there are dozens of other sizes which they are obliged to keep in stock.

A number of commission men were present, and objected to the point made by the doctor on small-size or under-weight sections. The "under-weights" were accepted readily. Consumers would ask, "How much is honey a pound?" The reply would be, for instance, "Eighteen cents." The consumer would call for a section. When the change was made out he would be charged only 16 cents; but let there be an over-weight section, and there would be complaint. Commission men seemed to prefer larger and thinner combs, of a trifle under a pound, and this is one reason why perhaps a 4½x4½ section, seven to the foot, has been coming into prominence. H. R. Wright showed his under-weight tall section, a trifle taller than wide. The display was a little better, he said, and consumers readily took it.

GRADING OF HONEY.

The discussion finally turned to the all-important question, *grading honey*. The system adopted by the Northwestern at Chicago was discussed pretty thoroughly. The first grade at that convention was "superfine." Grade No. 2 also calls for very fine honey; but the mere fact of its being classed as No. 2 puts a stigma upon it that it does not deserve. The Albany convention, as well as commission men readily saw the need of a change here. A large committee was appointed, comprising a number of prominent bee-keepers and commission men present, to draw up a new schedule of grading, and report to the convention. The report as adopted is as follows:

REPORT OF COMMITTEE ON GRADING COMB HONEY.

Honey shall be graded in two grades, the first to be known in the trade as "fancy," or "fancy white," and to be marked "A." It shall be composed of well-filled sections of light-colored honies. One face of each section shall be perfect in appearance, fully sealed, except the line of cells touching the wood. The other side of the section shall either be perfect in color and sealing, or nearly so.

The second grade shall be known in the trade as fair to good, white, and be marked "C," and shall be packed to meet the requirements of those desiring a good honey, but who care little for outside appearance. It shall be composed of honey thrown out of the first grade, irregular and travel-stained combs, sections not perfectly filled, but yet having but little unsealed honey.

White honey, third grade, mixed with inferior honey, including buckwheat and fall flowers, shall be graded by itself, and marked "M." We desire that combs so badly stained as to have the appearance of saffron be thrown into this grade.

Buckwheat honey shall be packed by itself and shall be marked "B."

Those bee-keepers sending to market boxes known as "pieces" shall put upon them a private mark of their own. This should also apply to honey-dew and any other kind not falling in regular grades.

I was out when the report was read, and now that it is sent in—well, it is not quite to my notion. W. Z. Hutchinson expresses himself in a private letter as being not quite satisfied. He and I were both in hopes the Chicago grading might be taken as the basis, and the *name* of the grades changed. But Albany aud Chicago are two very different localities, and it would be hard for them to agree upon one system of grading.

RENDERING WAX.

A paper was read by R. F. Holtermann, on some facts not generally known about rendering beeswax. By experiments which he had made, he was perfectly satisfied that wax is often overheated, therefore injuring it to a great extent for foundation.

Dadant took the ground that it was not overheating, but *steam*, that did the mischief; that it was the incorporation of water into the wax that made the trouble. Mr. Corneil was not of the opinion that overheating would hurt wax. In fact, in some experiments in melting wax in a double-walled solar wax-extractor, he had maintained a temperature, on a number of successive days, of 220 degrees. It might have injured it, but it was his opinion that it did not. Mr. Dadant then showed us samples of foundation, one in which too much steam had entered into the wax, and one in which it had not. The former had a milky color, and the latter was of a transparent beautiful amber. The former he made transparent by subjecting it to the heat of a gas-jet.

NEXT PLACE OF MEETING.

When we came to talk about the next place of meeting, a number of points were considered. We were very much undecided where to go until Captain Hetherington urged the claims of Washington. In a very neat and felicitous speech he made, it was evident that he had carried the day; and everybody began to talk and urge Washington. When it came to a vote by ballot, the decision was almost unanimous in favor of the city on the Potomac.

Washington is the Mecca, it was urged, of all true Americans; and every bee-keeper is a loyal man, and desires some day to visit the national capital. Some one else said that it would be a grand place to take the women-folks and children, and that what might be lacking in local attendance for the next meeting would be more than made up by those who had come to see the capital as well as to attend the convention; that is, a double interest would attract many, whereas the single interest of the bee-convention might not.

The election of officers resulted as follows: President, Eugene Secor, of Iowa; Vice-president, Captain J. E. Hetherington, of New York; Secretary, W. Z. Hutchinson, of Michigan; Treasurer, E. R. Root, of Ohio.

ALBANY CONVENTION SIDELIGHTS.

IN BETWEEN SESSIONS.

To me, the best part of any convention is the intermissions—the hand-shakings and the little chats with this one and that one. During the recesses there would be a lot of bee-keepers who would rush to the room where bee-keeping implements were exhibited. There were lots of hives and fixin's there. A variety of double-walled hives were shown, and other implements over which one bee-keeper would be very enthusiastic, and yet another one would not have them as a gift.

Several times some small bee-keeper would explain some new fixing of his own. Why, he had experienced lots of comfort with it during the past season, and wished his bee-keeping friends to know it. Some of the veterans—those who number their colonies by the several hundreds, would look on and smile, and remark, aside, "Good enough for *him*, but *we* can not tolerate such a roundabout way of doing things."

I had long wanted to see the extractor of W. L. Coggshall, that West Groton bee-keeper who produces so many tons of extracted honey, and there it was, among the other exhibits. He wouldn't have any of the commercial machines, as they are not made to suit him. He uses a Langstroth frame, and wants it to hang in the extractor just as it does in the hive. A very little talk with him will convince you that he has some very good reasons for such a preference. Of course, it makes the extractor large and ungainly. Why, it is as large as the Stanley automatic, and the combs are not reversible either. It is a four-frame machine; and instead of combs being put in the *four* sides of the basket, they are put in in pairs, with a strip of tin between. Of course, the two inside combs are nearer the center-shaft; but he says that makes no practical difference. The idea is not so crude as it might be.

Some one jokingly asked Mr. C. why he did not make his extractor large enough to take in a whole upper story, one on each side of the basket. A number of prominent bee-men were present; and as if it were a huge joke, they began to outline the plan. "Why," said one, "all you need is some sort of an uncapping-machine that will run between the combs just as they are in the hive. Then slip in a sheet of tin between each pair of combs. Put two supers of this kind in the extractor, and let it whirl. The honey will fly out and strike the sheets of tin, and drain out below; then reverse the supers the other side out, and start the machine, and, presto! there would be two whole supers, each containing ten Langstroth frames, with the honey all extracted, without so much as a frame being removed." I began to think of the Heddon supers, and the thought came to me that there were *possibilities* in the line of uncapping combs without removing a frame, especially with fixed frames. There was also a possibility of having sheets of tin so fastened that they would be held at equal distances; and these sheets or rack of spaced sheets could be dropped between the spaces between the combs. We all had a big laugh over the big invention, and it turned somewhat at friend Coggshall's expense. "See here," I said, "gentlemen, there may be a bigger thing in this than you think, taken in connection with the shallow extracting supers with fixed frames." Nobody can patent this, because reliable witnesses will testify that the invention was born at Albany, even if it does seem now like a big joke. Understand, I do not say it is practicable, but some day *something* might come of it.

I had a very pleasant visit with Captain Hetherington. The impression has, perhaps, gone abroad that he is a recluse, and a man who keeps all the good things to himself. Nothing could be further from the truth. He used to be prominent at conventions, and his name appeared frequently in bee-journals; but it entailed such an immense amount of correspondence, and brought so many visitors to his place, that he found he was obliged to withdraw himself from the public. As he was neither an editor nor supply-dealer, such an amount of correspondence, and so many visitors, not only became a great burden, but could be of no possible service to him; and he was too polite not to answer his correspondents, and too cordial not to entertain, and so the only alternative was to cut off the original source that brought it about. Now that we have so many excellent bee-books and bee-papers, I sincerely hope the day is past when it was necessary to go and interview and take the time of some of these extensive bee-keepers, at least uninvited, and during the busy rush of the honey-season.

I had delightful chats with J. H. Nellis, of the former *Bee-keepers' Exchange*, and with Julius Hoffman, the man who invented the Hoffman frame. I showed him our modified Hoffman frame for the L. hive, and explained to him how it was we were obliged to use a straight top-bar. After looking it all over he readily acquiesced with our modification, and said that it was better for the L. size. At one of the intermissions Mr. Hoffman favored us with some music on the piano. It was easy to see that it was a master's hand that touched the keys, for indeed he is one of the most accomplished musicians in the country. I was sorry afterward that I did not think in time to suggest the propriety of his favoring the whole convention with music. Perhaps he can at some future time.

Some of those large honey-producers of York State—those who produce their honey by the ton and carload, are a little sensitive about having their crops made public. One reason is, it creates a wrong impression, and leads outside bee-keepers to think that they are making a mint of money, and quite frequently it is the cause of others coming into their locality, and crowding upon their fields. When these large crops are published, small one-horse bee-keepers are apt to forget the enormous expense and labor required to harvest the crop; and when they come in, with little or no knowledge of the locality, they are sure to make a failure for themselves, and to seriously interfere with the average per colony of those bee-keepers who were first in the field.

While sitting at the dinner-table at the hotel, Mr. McKnight, of Owen Sound, Canada, gave us a very interesting account of the Colonial Exhibition in London, and how the Canadian honey was gathered up, how it was shipped, how it was displayed, and finally sold. The information he gave us was very valuable, and we hope he will some day give us the benefit of the information through an article or two, in order that the bee-keepers of this country who are about to prepare a mammoth exhibit of honey for the World's Fair may profit by his experience and suggestions. We will not attempt to reproduce Mr. McKnight's account here, as we fear we might not get all the facts straight.

W. Z. HUTCHINSON'S VISIT TO MEDINA.

WHAT HE THINKS OF THE HOME OF THE HONEY-BEES.

We were going to "write up" W. Z.'s visit here; but the following, taken from the December *Review*, is so much better than any thing we could give, we take pleasure in reproducing it instead.

This is written sitting at Ernest's desk at the "Home of the Honey-bees" in Medina, Ohio. Around me is the click of type-setting and type-writers, while from below comes the whirring sound of machinery in motion. For a long time I have desired to visit this establishment. I have often tried to imagine how I should feel when walking over from the station and looking up at that stone bee-hive over the inscription, "In God we Trust." Yesterday morning I experienced that sensation, and found it fully as pleasurable as I had expected it would be.

The first man to discover and welcome me was W. P. Root, the proof-reader and stenographer. We had often corresponded in shorthand. In fact, I once wrote an article on windmills in shorthand for GLEANINGS, and W. P. put it in type directly from the shorthand manuscript. He grasped my hand and said: "You are the man I have long been wanting to see," and led the way up to the office.

I had heard that nearly every visitor to the Root establishment had been surprised at its magnitude, consequently I had made up my mind that *I* was not going to be surprised, but I *was*. I was not surprised at the *outside* of the buildings—the illustrations in GLEANINGS have shown these quite fairly but it seemed to me as though they were about three times as large inside as they were outside. Medina is not a large city—about 2000 inhabitants—and almost from necessity many trades must be represented at this one institution. The sending-away for repairs, and delays from getting out of many things, would be too expensive. There are many things that Ernest said he would gladly drop, and rid himself of so much worry, but it seemed well-nigh impossible to do so. Ernest showed me over the establishment, then by a sort of tacit agreement he went about his work and allowed me to roam about at my own sweet will. You see, we were to go on together to Albany, and we both knew that we would have plenty of opportunity for visiting while on the road. The beauty of my visit was that everybody seemed to know me *at once*. This may be accounted for by the fact that every employe receives a copy of GLEANINGS. In five minutes the pressman and I were deep in the discussion of hard and soft "packing" for cylinder presses, of the kind of paper needed for the various kinds of work, the best inks, etc. Then he fished out his printers' magazines, and we looked them over. This is a fair sample of how I put in my time.

I don't remember ever going through so large an establishment where every thing was *quite* so neat and clean. Ernest remarked, in a joking way, in a recent issue of GLEANINGS, that if folks would only let them *know* when they were coming, they would have a "clarin' up" spell before their arrival. Of course, my visit was known in advance; but somehow I feel just as though there was no "clarin' up" spell on that account. Most of the rooms were just as clean as a dwelling-house; yes, far more so than some I have seen. Then every thing was so handy and convenient—so systematized! Each had a particular duty to perform, and the manner in which these duties were performed pleased me exceedingly. It was with a sort of pride in the work.

Yes, I went out with Ernest and looked at the bees. The apiary is very pleasantly located. The view lately given in GLEANINGS of the Shane apiary, after it had been brought home, is the only one that does justice to the beauty of the yard. This view, however, does not show the whole yard. The evergreens on the north and west sides stand in as neat and symmetrical rows as I ever saw. As an ornament and windbreak they are a success. Ernest is experimenting quite a little now as to the use or non-use of absorbents. It looks now as though absorbents might be an actual detriment. Let the bees seal the covers down tightly, so no moisture will escape, then use protection of some kind outside the hives, where the moisture can not reach it. The management of the apiary and of GLEANINGS is left largely to Ernest, while the business management is in the hands of Mr. Calvert. Gardening is Mr. A. I. Root's hobby now; the "boys," as A. I. calls them, being allowed a wide latitude in their departments. They are more given to the "trying of new things" than is the case with A. I., although no momentous step is taken without his advice or consent.

One of the new things that are about to be brought out is a reversible honey-extractor. It is not automatic, but the baskets can be reversed so quickly that but little time is lost, while much is gained in the way of making the can smaller, and in lessening the expense.

Yes, I saw that bright youngster of eight months, Leland Ives, who is now able to sit up in a high-chair and make a noise in the world. I did feel a little guilty for .coming away without calling on his new cousin, Howard Root Calvert; but he is so young that I feared he wouldn't take much notice of me.

As some of you may know, Ernest's hobby, or *one* of his hobbies, is that of photography; and when I tell you that he brought home his fourth or *fifth* camera on the day of my arrival, it is not to be wondered that his wife said, "What! *another* one?" using the same tone and expression that my wife sometimes uses when I bring home a new font of display type.

When I woke up in the night it took me some little time to decide that it was A. I.'s windmill that was going "squeak, squeak, s-q-u-e-a-k." "Yes," I thought to myself, "its master's hand is away in the West. If it were here that windmill would be—greased."

But, enough of incidents. I could fill the *Review* with them, but there are so many things that must go in this issue that I must close by saying, "Success to the Home of the Honey-bees and those who work therein."

[Brother Hutchinson in a few words has described very vividly the inside workings of the Home of the Honey-bees. If we do indeed deserve all the kind things he has said of us, we are pleased. We really were not aware that we kept things neat, although we have for some time back taken considerable pride in our system.

We had a delightful visit, and freely talked over all the kinks of the trade. No secrets or pointers were held back for fear that the "other fellow" might get the advantage. The feeling was that we were all of one family, and need not be jealous of each other's prosperity or new hits.

We enjoyed Mr. Hutchinson's visit because he is somewhat of a hobbyist himself. Yes, he guessed right. It was the fifth camera that we brought in that day. Mrs. R. does not object to the camera craze, only the wonder is, what we are going to do with so many instruments. Well, to tell the truth, by the death of a relative we came in possession of quite a lot of photographic apparatus. Two of the cameras are very fine ones, and we advertise them in this number for about half their original cost. Five cameras! Even *we* have no use for so many. Bro. H. is peculiarly graphic when he speaks of the windmill "squeak." We presume the senior editor will see this, and wonder whether it is squeaking now. After W. Z. H. spoke of it we forthwith sent a man up to oil it. It does not squeak now.

We not only enjoyed our visit together, but we traveled together to Albany, occupied the same sleeper and the same berth; and, as if that were not enough, when we got to the hotel we registered together for the same room; and, furthermore, we were frequently seen walking up and down the streets together. It was a sort of conundrum to many at the bee-convention how two bee-editors could with conflicting interests agree so well together. May this feeling long continue; and we hope the day of old jealousies between bee-editors is past and gone.]

GRADING HONEY, AND ITS IMPORTANCE.

HOW CHEAP GRANULATED SUGAR IS SUPPLANTING HONEY IN BAKERIES.

We perused with interest the article of Miss Wilson on page 960, and would respond thereto at length, but we desire first to learn the action of the Albany convention. However, one fact we will state; and that is, that the commencement at the Northwestern convention, relative to grading honey, was a step in the right direction; and now if a bee-man writes that he has a first grade of buckwheat honey we know that it is such. If he writes he has a third grade of basswood honey, we can also answer him intelligently as to what it would sell for in this market. Color and flavor should not be considered in grading, by any means.

A point that has been much argued, namely, "Does the low price of sugar affect the sale of extracted honey?" we desire to answer by stating that a manufacturing firm to whom in past seasons we have sold carloads of honey in one order writes that, after having experimented with granulated sugar, they find it far superior to honey, since the article manufactured, with honey as an ingredient, will sour in time, while with granulated sugar it will not; and since it is cheaper in future they will not purchase any honey. S. T. FISH & Co.

Chicago, Ill., Dec. 19.

[This is certainly not welcome news, if it is becoming general among bakers. We should like further information from others on this point, from those who are in position to know. By all means let us face the lion, if there is one, that we may be prepared to fight it.]

CUBA A BEE-KEEPER'S PARADISE.

AN INTERESTING LETTER FROM FRED CRAYCRAFT, OF JUVENILE GLEANINGS.

Dear Sir:—I am in Cuba. You will ask, "Who are *you*?" I will refer you to JUVENILE GLEANINGS of July, 1882, page 45. There you will see that you give a ten-year-old bee-boy credit for being the cause of your starting the "JUVENILE." You will see, on page 61, my name appears in connection with our friend E. E. Hasty as one of the boys who weighed the bees and their loads. I am still with the bees, and love them dearly. I came here from Astor Park, Fla., in October; and through the kindness of Mr. Osborn I secured the situation which I now occupy. Before coming to my new home I spent a few days with Mr. Osburn at Punta Brava in looking over his large apiary and admiring his mammoth extractor; and I also had the great pleasure of seeing it run. It is a fine piece of workmanship, and runs as smoothly as a sewing-machine. The apiary which I have charge of, called the "Two Sisters," owned by Mr. Manuel Gomez, Portuguese consul-general at Havana, is only a small one now, it being the desire of the proprietor to have the bees increased to an apiary of 500 or 600 colonies, and then put in an extractor run by steam. Mr. Gomez has contemplated having an apiary here for some time, and has built sheds to put the bees under, and also a large honey-house and workshop, all furnished with every thing needed for taking care of a large apiary; but he has not had time to give it his personal attention, he having one of the largest importing and commission houses in Havana.

The kind of hive in use here is different from the Simplicity. It is a two-story hive, the second story being used to extract from. The size of each is 13 x 16, and 10½ inches deep, each story containing nine frames 10x15, set crosswise to the entrance. When I came here the bees were not getting much honey, owing to rain and stormy weather; but we are having better weather now, and the bees are doing well. The principal honey source, the campanola, is just beginning to bloom, but there are always plenty of flowers here. The bees are working now on the royal palm-tree. It is similar to the cabbage-palmetto of Florida, only, instead of blooming two or three weeks, like the palmetto, it blooms all the year. As soon as one stem of blossoms is done, another takes its place; and a small apiary could store surplus honey almost all the year from that alone.

This is a beautiful country. Instead of being low and swampy, as many people suppose, it is high and rolling, with many hills that might almost be dignified by the name of mountains. The place where I am located is eighteen miles east of Havana by one of the finest roads on the island. The farm consists of about 800 acres, all in fruits, sugar-cane, and pasture land. There are a great many kinds of fruit here, among which I might mention oranges, lemons, limes, grape-fruit, bananas, plantains, mamayas, cocoanuts, mangoes, coffee, and many others that are strange to the eyes of an American.

In describing some of the many things to be seen here one can not fail to mention the roads. This is a limestone country, and the rocks are put to a good use in paving the roads. The road leading from Havana to San José, two miles from here and twenty from Havana, is as smooth as a race-track, and lined on each side with palm-trees. This is certainly the bee-keeper's paradise, and will one day lead the world in the production of honey.

FRED L. CRAYCRAFT.

Havana, Cuba, Nov. 17.

[We are glad to hear from you, friend Craycraft. We were about to say "friend *Freddie;*" but after all these years you must have grown to the stature of a man. We remember very distinctly the part you took in the early JUVENILE GLEANINGS, especially when you weighed the bee-loads *a la* Hasty. We trust the same spirit of investigation will follow you in your new quarters, and that you will give us further of your impressions in that land of flowers.]

LADIES' CONVERSAZIONE.

WAX BOUQUET OF AUTUMN LEAVES.

SOMETHING TO DO IN WINTER.

No prettier ornament for the parlor can be devised than wax leaves and flowers; and as winter is the time when bee-keeping ladies or their daughters have leisure for fancy-work, if ever, I will tell how to make a bouquet of autumn leaves; and next month, if desired, I will tell how to make a wreath of wax flowers, or a white cross in wax.

Leaves are made by pressing thin sheets of beeswax upon a leaf-mold until they are veined and cut off. First wet the mold. Cover a wire for a stem, with strips of wax pressed around smoothly, or use one covered with thread (such as are used in ladies' hats). Lay the stem on the whole length of the leaf; then lay on another sheet of wax, and press on tightly (but do not press on the wire) till cut off smooth all around.

For autumn leaves, use thin sheets of yellow beeswax—just such as are used to make foundation for sections; the thinner the better, so that there are no holes in the wax. Wet the mold; press on the yellow wax, and cut off; then, while the leaf is still on the mold, rub on to it some red, green, or brown paint, as fancy dictates. Do not rub on too much, as the lining will not stick. Now lay on a stem covered with wax, and press on the mold again another bit of yellow wax. This last forms the lining to the leaf. Now press on around the edges until they are cut off smooth. The room should be warm, so that the wax will work easily and not break —just comfortably warm is sufficient.

The leaves may be made entirely of beeswax which is more pliable than what we buy, or the upper surface may be made of sheeted wax prepared for the purpose, and sold in packages generally kept by druggists, or it may be ordered by them, both green and variegated.

After the upper surface of boughten wax is made, lay on the wire stem that has been covered with wax, and for a lining use sheeted beeswax. If the upper surface is green, or nearly so, then the lining should be of green wax. But if the upper surface is of yellow wax, to imitate an autumn leaf the lining should be of yellow wax also; and as the wax we buy is so brittle I always prefer to use a lining to the leaves of beeswax.

There should be a variety of leaves made, to look well in a bouquet, placing the smaller ones at the top, and grading down to the largest for the bottom leaves. Begin at the top to nail them on to a prepared board lined with white paper. Nail each leaf on separately, then the next leaf so as to cover the stem of the one above it, and so on until all the stems are covered and the leaves nailed on. Now finish by making a few large green stems, and press on underneath the leaves, causing the cluster of leaves to look as if one could hold the bouquet in his hand by the stems. Around the stem arrange a wax ribbon so cut and stuck on as to imitate a ribbon tied in a bow-knot. Cut each bow separately, and stick on; then the short strings below the bow, and stick each one on separately; then a short strip of the wax stuck on in the center, to form the center knot.

Four or five leaf-molds will be needed to give the best effect, although a very pretty bouquet may be made on but one or two molds.

For sheeters to make up sheets of green wax and small quantities of yellow wax, I form them of plaster of Paris by stirring up a pint bowl half full of it and pouring it into a large breakfast-plate. Before this hardens, put in something iron for a handle—three or four large nails stuck into a potato, with the heads all even; then hold the heads down into the plaster until it hardens, just escaping the bottom of the plate. In 24 hours heat the plate and then take it out; soak it 10 minutes in lukewarm water, then dip it into the melted wax (previously colored with a little thin bag of green paint, Paris green, pressed out with an iron spoon). Do not use too much green paint, as it makes the wax brittle. Dip again into the water, causing the wax to peel off the sheeter just as it does in sheeting wax to be pressed into foundation, except that this sheeter makes a round sheet. Yellow wax may be sheeted the same way, but not colored. If the wax is too hot it will be full of bubbles, which should be skimmed off, as they will make the sheets full of holes; and if too cold, the sheets will be too thick. Do not try to make flowers out of such wax, as it is too thick; but it is just right for leaves.

After the leaves are formed into a bouquet, tack on the side pieces, which should be about an inch and a half or two inches deep, forming a box to preserve the leaves from being broken. Over this may be tacked a pane of glass; but a picture-frame looks much better.

Use some green leaves in the bouquet, and rub on to the yellow. Use quite freely of red, brown, or green paints, so that the bouquet may not have too yellow an appearance.

The leaves should lie flat, yet stand out distinct from each other, nearly touching the glass.

Wire stiff enough to hold the leaves in place should be used. Do not use long wires, but tack each leaf on close to the leaf, with a carpet-tack. The board to form the back should not be too thin—⅜ of an inch is about right. Use a small hammer, and a nail-set to drive the tacks with, and cover the heads with other leaves or green moss. Line the box with white printing-paper.

A few dead and dried bees stuck on are pretty; but as honey-bees dry up so small, I prefer queens or drones, or butterflies. Stick a small black-headed pin through them before they are fully dried, and stick it through a leaf. The yellow-headed bumble-bees also look natural on wax leaves or flowers.

POTATO-BALL BREAD.

This is the bread for swarming-time. Why? Because it never sours within any reasonable length of time. If made up at night, and mixed the first thing in the morning, it will be ready to bake before the bees begin to swarm in the forenoon. Or, the yeast may be set in the morning, and attended to through the day just when there is nothing else pressing, only so that it gets light; but it does not sour by being left some time after being light. It may smell somewhat sour; but by being mixed it takes the sourness all out of it, although it may have been as light as a puffball, and is always good if not allowed to get too light before being baked.

HOW TO MAKE IT.

Take two or more fresh yeast-cakes and soak them soft. Stir into a pint of mashed potatoes the yeast, one teaspoonful of salt, one teacup of sugar (half a cup of sugar will do after the yeast has been started). Use no water nor flour. Set this away for four days in summer, or one week in winter.

To make bread, take one quart of finely mashed potatoes, cool enough not to scald the yeast. Stir the potato-ball in thoroughly, and save out two-thirds of a pint for bread next time. Now stir into the remainder about one-fourth teacup of water (use no flour), and let it stand over night or until light; then add one quart of water, and flour enough to make a sponge. Beat well and let it stand until light again, or until you are ready to mix (it never needs soda to sweeten it); then make out into loaves. Oil the top of the loaves; when light, bake in small loaves, as such do not require being baked so long as larger ones, consequently the crust is not so hard. If two loaves are made in one pan they may be broken apart to see when done, and yet not injure the bread. If one has any trouble to guess when the bread is done (as bread is often injured by being baked too long), handle gently when setting it in the oven, as jarring and shaking will not allow of its being so light.

If graham bread is wanted, use half the potato sponge for graham sponge, and the other half for white bread. When light, mix it stiff with white flour, and treat the same as for white bread, only be careful not to get it quite as stiff as for white bread. If too stiff, work in more water. Both the white and brown bread should be made up so stiff they do not require more flour when worked out into loaves.

Bake it nicely, neither too fast nor too slow, and you will have good bread every time with even fair flour. Much bread that otherwise would be good is spoiled in baking.

The fire to bake the bread should be started immediately after the bread is mixed into loaves. If there is fire in the stove already, and the oven-doors closed, and the damper to heat the oven adjusted, all well; but if there is no fire, then it should be started before the bread is made out into loaves. Many persons wait until the bread is ready to go into the oven before any attempt to heat the oven is made, which carelessness allows the bread to run over, or get too light, and then the fire is hurried up so fast that the bread is burned. The heat of the oven bakes much the nicest after being heated quite hot, and is beginning to cool. Often the last loaf baked is baked the best.

SMALL POTATOES.

These may thus be used up for bread, as the large ones are nicer for table use. I put them into a wire basket and set them in a kettle with plenty of boiling water. When done, lift out the basket and pour a few into the potato-masher while hot. Press the lever, and the potato is pressed through the perforated metal. The skins are retained in the masher. This leaves no lumps in the bread, uses up the small potatoes, and saves time and potatoes in paring them.

By the way, this same potato-masher makes potatoes very nice for table use. Boil nice large ones, and, just before sending to the table, run them through this masher, sprinkling in a little salt, or salt in boiling. As fast as mashed, pour out into a dish, and cover them. Pour over them some hot rich cream, in which a little butter has been beaten up, and you have a most delicious plate of potatoes as light as a puffball. Do not stir them after being mashed or pressed through the masher, as it will take the lightness out of them.

I mention the above way of making bread, because, in swarming time, it sometimes seems very difficult to get bread made when the cook has the swarms to look after. Two summers I have had help who could not make bread. Though I had three girls one summer, none of them could make bread, and were inexperienced in bee-work also. The bees swarmed incessantly that summer, and gathered much honey. Mr. Axtell took sick about that time, and I had both yards to look after. With the help of the girls, I could only get time to mix up biscuit dough and bake for bread in the morning before bee-work began.

Another summer I undertook to mix light bread outdoors where I could watch the yeast when light, as I had set it in the sun to rise, as the girl could not make bread, and was inexperienced in bee-work also. I had just got my hands into the dough to mix the bread, when out came a swarm. I rubbed off the dough and ran for the queen, and took care of the swarm. By this time the dough had dried pretty well upon my hand, which took me a long time to wash. I had just got into the dough again, when out came another swarm. I could not take time to get the dough off my hands very well, for I was afraid I should lose the queen; so I found from experience that bread - making and queen - catching did not work well together.

VENTILATION THROUGH THE HIVE.

In your article on page 889, in the Nov. 15th issue of GLEANINGS, you say so many bees died in hives that were not protected by outside cases, I wondered, as I read, whether there would have been the same loss if there had been passages through the center of the hive, *a la* Heddon or Mr. B. Taylor, or holes punched through the tops of the combs, as we used to do a good many years ago for winter passages. I have seen the same things happen to colonies we were preparing for winter, and had set some of the brood-combs outside of the division-boards for the bees to carry the honey in. One cool night had caught them, and they drew up into a cluster, leaving small clusters on the combs that were outside the division-board. These bees seemed dead when found; but if the bees were let alone, and a warm spell was not too long in coming, I think they warmed up and crawled back into the hive again, just as I have seen bees do when I have fed them out of doors more syrup than they could carry in before it became too cool in the evening. They would be seen sitting around upon the feeder, as if dead; but if, next day, the warm sun shone upon them they would all or nearly all revive and fly black to their hive. But I have an idea that such exposure shortens their lives.

Evangelist J. E. Wolf, who is editor of *John Three-Sixteen*, says, in the November number, "Mr. Harry Lathrop, of Browtown, Wis., sent us about 40 lbs. of the finest honey it has been our privilege to test for a long time." I suppose it is known that Bro. Wolf is, with other helpers, carrying on an Indian orphanage and training-school in Vinita, Indian Territory. The funds that sustain them are given in answer to prayer, and by friends of the mission. Just now the little orphans, aged from 8 to 16 years, are in need of shoes and stockings, as winter is coming on. There are a thousand other ways in which help would be appreciated just now. Will not many more brothers and sisters remember Bro. Wolf and his large family of orphan children, with substantial aid now as the holidays draw near? Remember the words of the Lord Jesus, "It is more blessed to give than to receive." I will send you two pictures of the older orphan children. MRS. L. C. AXTELL.

Roseville, Ill., Dec. 19.

POULTRY-RAISING.

HOW NOT TO HAVE FAILURES; BY A BEE-KEEPER.

Ever since reading Mrs. Smith's letter in GLEANINGS about raising poultry, I have felt like telling a little of my experience. While what I have to tell may be nothing exactly new, still there may be something that may be a help to her.

We generally have pretty good success with our poultry, and raise a good many chickens, ducks, turkeys, geese, and guineas. The first thing to be looked out for is the parent birds, which should be two years old, to have the best success. If they are younger, the offspring are apt to be weak and delicate.

The next thing is food. Perhaps some people can feed all other poultry the same as they would little chickens, and have good luck with them, but I can't; for while little chickens will thrive and do well if fed plenty of corn meal, no other kind of poultry will, for me at least. When they are small, the best food for them is bread and milk, or cheese made from thick sour milk, and seasoned with a little pepper and salt, just the same as though it were to be eaten by boys and girls in place of baby turkeys and geese. As they grow older, scraps from the table, and almost any thing except raw corn meal, will do for them, and they will pick a great part of their living if allowed to run.

The next, and perhaps a still more important point, is to keep them *dry* and *warm*. It will not do to provide them with good coops and think they will take care of themselves, no matter whether they have hen-mothers or mothers of their own kind. A run through the wet grass in the early morning, or a cold drizzling rain, will put an effectual damper on the enthusiasm of almost any poultry man, or woman either. Although water-fowls, little goslings and ducklings become chilled, and die, just the same as little turkeys, if they get wet, even when they are nearly half grown; so we make a yard around their coops. A board one foot wide is high enough to keep them in in the morning till the grass is dry, or on days when it is rainy.

Last spring, about the middle of May we had over fifty little turkeys, and some ducklings and goslings, when there came a cold rainy spell that lasted for three or four days. The ground, and every thing outside, was thoroughly wet and chilled. I put the little fellows in some large boxes, and brought them into the house and kept them by the fire (the mothers were left outside), till the storm was over. A few of them died; but over twenty of the turkeys went to market for Thanksgiving, and there are some more to go for Christmas. They brought a good price, as they were early, and so were large and well grown.

MRS. A. L. HALLENBECK.

Millard, Neb., Dec., 1891.

A NUT FOR DR. MILLER TO CRACK.

Please ask Dr. C. C. Miller what he means by the expression, "Pretty good for Missouri." Did he not know that he would stir up a hornet's nest? Why should not Missouri, with an area nearly equal to all of New England, be up with most of 'em? Where is the State that has greater natural advantages in honey flora, climate, and all that goes toward making successful bee-keepers? And then to have one of the big doctors say, "Pretty good for Missouri," as though we were some out-of-the-way corner, when in reality we are the very heart of this great United States! Now let him rise and explain. MRS. J. M. NULL.

Miami, Mo.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

THE NEW FRAME; A REVERSIBLE HOFFMAN.

I am glad that bee-men are coming to reason as to frames being spaced. What an idea, to do a thing at guess as one has to with a loose frame!—no room in one place and too much in another. Again, what a sad blunder it was to use a ⅜ top-bar—sad unless we reversed often.

The cuts of your frame in last GLEANINGS show some very excellent frames. I shouldn't like the narrow bottom-bar, for it is a loafing-place for bees. I mean to use all the room to good advantage; and to fill the frame, I will reverse. I have a reversible wire of my own, and I'm now working on a hive to reverse, and use the regular Hoffman frame. It is a wonder to me how a frame closed the whole length, and close to the hive-ends, can please one. I bought one such this fall, and it was impossible to get a frame out—perfectly glued everywhere. I shall transfer them in the spring.

I can hardly see the need of a follower in your hive. Why not wedge the ends of frame, and save so much extra? Make a wedge one way ¼ wide, one way ⅜, and you can make one width answer. I know that extra board makes more work and cost, and takes up valuable room.

Hallowell, Me., Dec. 21. E. P. CHURCHILL.

[All that is necessary to make a hive of Hoffman frames reversible is to wedge or key up the frames. Lay a couple of sticks ⅝-inch square across the frames, and at each end. Put a bottom-board on, turn the hive over, replace the cover, and the work is done. Leave the hive thus until the bees have built the combs down, and then restore to its normal position. With the Dovetailed hive this can be done very nicely. We put in a follower or division-board because, when removed, it gives more room for handling frames. Many times all that is necessary is to pull out the follower, shove the frames apart in the center, look down between the combs, and close up without removing a frame. Then for any thing less than eight frames the division-board is a necessity. This often occurs when preparing for winter, or in queen-rearing.]

THE NEW TOP-BAR; THE MOLDED COMB-GUIDE NOT NEW.

In the last issue you say, "It seems almost a wonder that somebody did not think of this before." Somebody did think of this. The triangular top-bar comes pretty near it, only the little buzz-saws would persist in making the bevel a plane instead of a concave surface. About fifteen years ago a sash and blind factory in Vermont made some top-bars in just this form by running them through the "sticker," which was provided with knives ground in the form of two intersecting arcs of a circle. The frames were made to order for a neighbor of mine. I believe they were quite satisfactory, yet we did not recognize any gain in making them concave.

An advantage in making the bottom-bar narrow would be found when we attempt to lift a frame from between two others, the narrow bottom being less likely to crush bees or scrape the adjoining combs. A disadvantage is, that this form is no better adapted to winter use than the loose one.

In your experiments in wintering, why not try a few colonies in single-walled hives outdoors? It would act as a check upon hasty conclusions, and help to determine how much of your success is due to the hive and packings, and how much to thorough preparation beforehand. W. H. Upton.

Morning Sun, Iowa, Dec. 21.

[The top-bar you describe is not exactly like our own. Our cut, as we explained, did not quite do justice to the comb-guide. This latter projects down about ⅛ inch below the two intersected arcs, forming a bead, and an excellent place for the fastening of foundation, as we shall shortly explain. In your top-bar you discovered no gain because there was practically no comb-guide. Our top-bar has the comb-guide part and parcel of it.

We did not claim that there was any advantage in such a bottom-bar for wintering. It *couldn't* make any difference.

In regard to wintering in single-walled hives outdoors beside those in double-walled hives—that is just what we have been doing. Bees in single-walled hives have died for us before the first of January. We have had most disastrous results in trying to winter outdoors in hives not protected. We don't think, but we know, hives must be protected with cases.]

USING STARTERS FOR WIRED FRAMES; A QUEEN WHOSE PROGENY WOULDN'T RAISE DRONES, OR SWARM.

I see articles in every Gleanings about wiring frames. Now, I let the bees do most of their own wiring. I do it in this way: I wire the frames as you recommend in A B C; put in a starter about 2¼ in. deep; put the frame between two full frames of comb and brood. The result is, that I get the comb built clear to the bottom-bar, and no sagging, as straight and smooth as a planed board. As a rule, by the time the comb is built down it is full of brood. I also put it the same way in the upper chamber, where it works as well. I do not think it pays to use full sheets of foundation.

Now about a queen you sent me last year, a select and tested one. Last spring I wanted to raise some early drones if I could, so I fed well and put drone comb into the brood-nest, but I could not get a drone. I tried all summer to get her to fill a frame of drone comb, but could not get her to lay a drone egg. She filled the brood-nest from a four-frame nucleus to a twelve-frame colony, with eggs. Besides that, I got 42 lbs. of extracted honey; and if there is a non-swarming race of bees I think her bees belong to it, as there was not a swarm cast from that colony. I received her a year ago the 21st of last September.

Dr. C. H. Peabody.

Providence, R. I., Nov. 21.

[You can use starters, and the bees will build them out into combs over wires; but you are liable to get drone-cells instead of worker-cells. For this reason the majority of bee-keepers decide that they must have full sheets of foundation in the brood-nest. The rearing of many drones is pretty apt to be prognostic of swarming. Inversely, the rearing of *no* drones means little or no swarming. It has been noticed, also, during the past summer, that drone-traps at the entrance curtail swarming because they kill the drones. Therefore one reason why the progeny of your select tested queen did not swarm was because no drones were reared.]

HOW TO MAKE A DAMP CELLAR DRY FOR BEES; INFORMATION WANTED.

Can some one tell me how a bee-cellar can be remedied to prevent it from being too damp during the time the bees are confined therein? The cellar was dug eight feet deep with good thick walls from the bottom to the top, and the floor made of cement. The land lies perfectly level for quite a distance around, and a race of water runs on the west side about 8 rods from the cellar. The soil is what would be called clay for the depth of 6 feet, then comes sand. The cellar was so damp last winter that it molded the combs considerably; and as the old bees crawled out and died, they, too, would become moldy very soon thereafter. There was an abundance of good ventilation in the cellar. This cellar has cost the owner now not far from $100, as it now is, and he does not like the idea of casting it aside and building something else, so he asks if there is not some way the evil may be remedied without going to the expense of making another. A.

[If your soil is porous, with a race of water so near as you say, it would be difficult to make the cellar dry. A grout cement bottom is supposed to remedy the evil if any thing will.]

HOW TO RENDER OUT OLD COMBS.

I wish to ask what is the best method of extracting the wax from old combs. Do the extractors accomplish that object better than any other way of separating the wax from old combs; i. e., can you get more wax than by boiling and straining and using a squeezer? I should like to know the experience of your contributors. It is certainly a rather unpleasant job when done in the old-fashioned way of boiling and straining. A. P. Fletcher.

Ludlow, Vt., Dec. 15.

[The Dadants say, Wait till cold weather, and then mash 'em all up fine, after which render them by any of the well-known methods. There is no better method for getting out all the wax than by boiling, straining, and squeezing the residue, no matter by what kind of machinery it is done. It should be remarked, however, that none of the residue should be thrown away. It should be treated to sulphuric acid, as described in last year's volume.]

THE NEW DOVETAILED CHAFF HIVE, AND HOW IT PLEASES.

The five single-story chaff hives I purchased of you in the flat last month went together nicely. Every piece was accurately sized, and the whole of good material, and made in a workmanlike manner. I transferred my bees to them with ease. They will surely be a successful outdoor winter hive, and for summer they are just as handy as the single-walled hive. You have not asked my advice, and may not thank me for it; but I would suggest, however, that, if the covers were made one inch wider they would be better, as the slight margin they now have will sometimes let the wet in. JAS. S. SIMONTON.

West Richfield, O., Dec. 12.

[We make a wider and deeper cover for those who prefer it. For winter use it is not intended that the flat cover shall be put on the hive. Put a super on, and then the covers.]

THE LARGE AND SMALL BEE-KEEPER, AND TINKERING WITH TRAPS.

It is quite amusing to read the descriptions of the many traps and notions that some of your correspondents seem to regard as absolutely necessary to success. One who keeps a few colonies of bees for pleasure may enjoy "tinkering" with all the "new notions;" but for those who keep bees for profit, and keep them by the hundreds or thousands, as is done by many persons in California, it won't pay, and there is no time for fooling in these large apiaries. Many things that might be applicable in the East would be useless here. DELOS WOOD.

Santa Barbara, Cal.

[Yes, there is a difference in localities, and a difference in bee-keepers. We can't all like the same thing.]

WHAT IS A GOOD MAN IN THE APIARY WORTH?

How much can the owner afford to pay, per colony, to a practical apiarist, in money, to manage, say, not less than 250 or 300 colonies of bees that are in good condition and in a fair location? The owner is to furnish all material necessary for the successful management of the bees. The apiarist is to furnish all the labor. How much when bees are in bad condition and in bad hives? S. B.

[We would advise hiring your help by the day. It would be difficult if not impossible to make a fair schedule on the other plan. Labor in the apiary is worth from 25 to 50 per cent more than common labor, and the price of this varies as to locality.]

MOLES IN THE APIARY; HOW TO GET RID OF THEM.

I should like to have some information on the following: I have on my farm, south of this city, an apiary of fifty colonies. They are located on the south side of my residence, and I do not care to move them; but moles are undermining the ground in that particular place so badly that my hives are sinking into the ground. What can I do in this case?

Columbus, O. EARLE CLICKENGER.

[We would not move the bees, but poison the moles. "Rough on Rats" ought to exterminate them. If you do not like to use poison, procure a good cat or rat-terrier.]

BROMIDE OF POTASSIUM; A CAUTION.

Friend Root:—I wish to call your attention to what Dr. J. H. Kellogg says in *Good Health*, Nov. No., page 341, about bromide of potassium. He says, "A vast amount of harm has been done by the use of this nostrum." Some years since, I received apparently temporary benefit from the use of this drug, and was told by our family physician that it would do me no harm; but I very soon found out that it was injurious to me, and I quit the use of it. W. P. ASPINWALL.

Harrison, Minn., Dec. 4.

PURE ITALIAN QUEENS THAT ARE BLACK.

I had an occasion to start a lot of queen-cells, and one of the second lot of queens turned out to be black. She was as black as the blackest lump of coal you ever saw. I kept her, and she throws good Italian bees. Did you ever know of a jet-black Italian queen?

Buffalo, N. Y. JAMES ROBINSON.

[We have had Italian queens that were perfectly black, and yet their bees were perfectly marked Italians with three distinct yellow bands, and, besides this, they showed all the other qualities of pure Italians. This is a fact we have mentioned in our price list. Italian queens may be any color from black to yellow, but their bees should show three yellow bands.]

A DISAPPOINTING SEASON.

The past season has been rather disappointing to the bee-keepers in most of New Jersey. Although both clover and buckwheat were never more promising than at the opening of the past season, yet, owing to excessively wet weather following, my yield from 58 colonies was but 995 lbs. W. W. CASE.

Baptisttown, N. J., Dec. 1.

THE FIVE-BANDED BEES.

On reading the report of Mr. Wm. L. Ewing, page 930, 1891, about five-banded golden Italian bees, I wish to say that I have tried them and found them very gentle to handle, and fine honey-gatherers. I must say that they did better than the three-banded. R. E. SMITH.

Tilbury Center, Ont., Can., Dec. 8.

1000 LBS. FROM 11 COLONIES, AND INCREASED TO 24.

It has been a very good year for bees. I had 1000 lbs. of comb honey from 11 colonies, spring count; increased to 24. G. J. HOBART.

Westford, Vt., Dec. 7.

[You have done exceedingly well.]

Can you tell me what is the cause of brood-combs being of a moldy color at this season of the year, when there is a strong colony of bees in the hive? G. A. LATIMER.

Norfolk, Neb., Nov. 25.

[Dampness is the cause. The use of absorbents will cause this. It will probably do no harm.]

GARDENING BETTER THAN BEE-KEEPING.

Gardening pays better than bee-keeping here, although I am much attached to my bees; but the range is not good for them.

JOHN FRANKLIN.

Round Rock, Texas, Dec. 18.

A California cherry-grower claims that bees are necessary to grow a successful crop of cherries, and says that the question is, to bee or not to bee.—*Rural New-Yorker.*

DR. MILLER'S PLAN OF WINTERING ALL RIGHT.

Tell Dr. Miller that I have wintered with perfect success in single-walled hives packed with straw, similar to his plan, only I left them where they stood, and put a cushion over the frames and piled straw up around the sides. All my hives face the south; and unless the winter is severe I do not protect the south side. If you use good long oat straw there is no trouble about its wetting in; at least, I have had none in six years' experience. The only trouble is its untidy looks; but if it is neatly done it doesn't look so bad. It is no more trouble to put on and take off than outside cases, and is decidedly cheaper; and, besides, there is not a lot of loose traps to house. We have to winter outdoors here, as all the cellars are very damp. Do you remember my speaking of having trouble with my bees going to a neighbor's well of soft water last summer? Well, I took A. I. R.'s advice, and drilled for that vein of soft water, and got it; and since then my bees trouble nobody's well but my own. JOHN BURR.

Braceville, Ill., Dec. 21.

THE KAWEAH COLONY A THING OF THE PAST.

A few months ago I wrote GLEANINGS a letter, denouncing the above colony as a fraud and a swindle (see page 595 for July 15, 1891). I received some very sharp replies to said article. As I stated, I had investigated the workings of said colony, and I *knew* there was dishonesty and rascality in the management to such an extent that it was sure to come to naught. A few rogues were gaining money in handsome sums of the poor, honest, and confiding toilers, by misrepresentations. *Lies* were the game. I am happy to inform your readers that Kaweah Colony is a thing of the past. It has gradually sunk into its inevitable fate. It is dead—so recognized by its leaders, and almost if not all of its members here in Tulare County. They have sent out a circular to that effect, and several leading papers have published long articles on the same. J. G. GILSTRAP.

Last, Cal., Dec. 25, 1891.

PURE GRANULATED SUGAR FOR BEES.

Friend Root:—It occurs to me that the subject of pure sugar for food for bees is one of national importance to bee-keepers, and ought to receive the attention due it. Last fall I fed two colonies with syrup made of granulated sugar, with about ¼ extracted honey added. I now find that the sugar is not only granulated, but caked hard in the combs.

We are having nice warm weather, bees flying, and I have taken advantage of this to examine some of my bees, and I fear I shall lose the two fed with sugar. I have seen it stated somewhere that confectioner's "A" sugar is better and purer than granulated; that bees fed the granulated went through the winter in a weakened condition, and would soon die out. I am no chemist; but this seems to me to be very reasonable. Could not Prof. Cook analyze the two grades of sugar, and report through the bee-journals? Can't you arrange to have him do it? Would it not be better still to have a pure sugar manufactured especially for bee-keepers—one that would not easily granulate? It occurs to me that the Bee-keepers' Union could arrange with some reliable manufacturer to have such a sugar made and sold to bee-keepers at wholesale prices for about the same as granulated sugar. It might be furnished to members of the Union at wholesale prices, and charge a small advance to those not members. This might be the means of greatly increasing the membership of the Union. I am going to join the Union myself this coming year, and expect to remain a member of it. If such a sugar is made I will take 10 barrels next July, and would take 15 to 20 barrels every year thereafter. I would also suggest that it be put up in barrels of a uniform size of 350 lbs. each. T. K. MASSIE.

Concord Church, W. Va., Dec. 23.

[We have not been able to detect any difference in granulated sugar. We have used a great deal, in feeding, that made from the beet, and some from cane sugar, but we were not able to notice any difference in results. We have always regarded granulated sugar as a pure article, and the most uniform and pure of any sweet known. It is next thing to impossible to adulterate it with cheaper sweets, and yet have the fact concealed. Still, we may be mistaken, and therefore solicit facts from those who are in a position to know.]

NOTES OF TRAVEL

FROM A. . ROOT.

AT COLORADO SPRINGS.

Dec. 1.—I met Prof. Cook, his good wife, and their son, Albert Cook, but we usually call him "Bert," for short.

As I described things fully, three years ago, along here, I have not thought best to write them up again now. Bert is a fine strong active boy of 18, and bids fair to be his father over again.

Although we were having very fair summer weather, I told my companions that, before we got over the mountain summit, we should have winter, and perhaps sleighing; but they laughed at my prediction; but when a two-horse sleigh at Leadville took us from the station to the hotel they began to have more respect for my knowledge of mountains and altitudes. Bert took occasion, after supper, to have a skate in a city whose altitude is greater than any other of its size in the world. One would suppose, of course, that lead was the principal mineral in and around *Lead*ville; but not so. Gold and silver are the minerals that give the place its celebrity. The grand canyons of the Arkansas and Rio Grande, with their rocks and strata, gave, of course, much food for talk and study; but Prof. Cook tells us that geologists nowadays do not give earthquakes much credit in accounting for this wonderful region. The contraction of the earth in cooling, and the action of water, which has very evidently, at some time, covered much if not all of this region, it is thought, has done most of it.

The convention at Salt Lake City, Dec. 3 and 4, was fairly well attended, and our efforts resulted in getting well under way a *permanent* organization. This seems much needed for several reasons. Foul brood has been making great havoc in some localities around here; and for some time back, but little has been done about it. The market price of honey has also been a good deal demoralized. The price has been allowed to go down because no one has gathered up the product and sent it off where it would command a proper price. I am greatly indebted to two bee-friends, Henry Taufer and J. C. Swaner, for making my visit pleasant. Salt Lake has now over 50,000 inhabitants, and over 75 miles of electric street-cars. Three years ago such a thing was unknown here; but now they have runs equal to 12 miles in a single straight line, and they run up the mountain-side, and along the "mesa"* wherever cottages are found, until horses and wagons are almost unnecessary. Here I first found cars *heated* by electricity. I have long been expecting this; and now, dear friends, electricity is here, ready not only to light our houses and do the work, but it is already giving heat. Heat, light, and power are given where wanted, through the medium of a simple wire. Let us hunt up all sources of power not only our natural waterfalls and rivers, but our artesian wells, gas-wells—let us gather the power they give, then with a simple wire we have power to carry ourselves and our burdens from place to place; light to make our cities and dwellings as bright as day, even at midnight; and last, but not least, *heat* to warm our homes comes also, along this self-same wire. To warm a car, they have a heater in each corner, under the seat. I burned my fingers in exploring into it, so I ought to know. Yes, I fully believe that, through the medium of electricity, this restless and at times unmanageable servant of ours, *the wind*, is ultimately to give power, light, and heat; and it is to be made *tame*, *steady*, and *docile*. You see?

---

*Mesa is a Spanish word meaning *table*, or any level spot on the mountain side or summit.

ONE OF OUR ENTERPRISING BEE-MEN.

Woodmansee is already talking of getting power to run his bee-hive manufactory from one of the street-car companies; and he says if he could use the power all the time (they rent it by the month) it would be cheaper than steam.

Natural gas has just been added to the long list of Utah's natural products; and yesterday (Dec. 7) a party of us went out by Great Salt Lake to see a new well. The gas has a pressure of over 100 lbs.; and when let off it is the greatest "mud-slinger," perhaps, the world ever saw. Some of the papers suggest that it be utilized in the next *political* campaign. Well, it has covered the tools and derrick, and the landscape for acres around, with the mud it has belched forth. In some places we found great holes in the ground, big enough to bury a small dog, made by immense chunks of mud hurled to such a height that, when they came down, they buried themselves and left a hole above them. After we had examined the well, as it was winter weather our party of about thirty adjourned to the nearest house, owned by E. Garn, Centerville, Davis Co., Utah, to get warm. Said house is warmed by natural gas, and has been for five years past. He drilled, or rather drove, down an iron pipe about 60 feet. He got water and gas too, and, like a Yankee, he put a tight barrel over the top of the tube. Near the bottom of the barrel a stream of water runs out constantly; and exactly in the top he put a tube, made part of iron and part of rubber hose, so as to carry the gas into his cook-stove. While we were tramping the new kind of mud all over his floors I happened to look out of the window and saw quite a row of bee-hives. Don't it beat all, how you find a bee-man around when you least expect him? Pretty soon they bantered him for honey; and before the train got along he had loaded up almost every last man with one or more sections of alfalfa honey. Our crowd had rather more knowledge of bees (but a little less silver) when they boarded the train. I was rather glad, for it will cost him something to clean up his floors. His honey was all stored in 1-lb. sections, of course.

In this region artesian wells are so common that, when a farmer wants water in a particular pasture lot, he just drives down an iron pipe, and then lets the water pour over into a trough. In one place the well had made the ground so swampy that they tried to plug it up; but the plug didn't fit very well, and so it sent the water in jets on the trees and every thing around, where it had frozen in all sorts of comical shapes. I mention this only to illustrate how not only *water* but *power* is allowed to run to waste just through neglect, and, shall I say—stupidity? In the same locality are hot springs—almost as hot as you can bear your hand in the water. It comes out from under a beautiful natural boulder—a boulder so large that it is a small mountain, and the water is most wonderfully clear and sparkling, even if it is hot. Well, the pebbly bottom is composed of patches of the most brilliant blue, green, yellow, and, in short, almost all the colors of the rainbow, these colors being, I suppose, caused by the precipitation of the various chemicals found in the water. It boils and bubbles up in such volumes that it would fill, I think, a twelve-inch pipe, and then it goes steaming off across the fields until it finally forms a warm lake; and as it doesn't freeze over, ducks and water-fowls come there to swim all winter long, making it a favorite hunting-ground. No one has yet ever undertaken to utilize the immense quantities of heat going to waste here. It would heat greenhouses and hotbeds, miles of them, and would comfortably warm all the dwellings in a fair-sized city. The temperature is absolute and steady, and the expense nothing, after the pipes are laid to lead the water. At present it is utilized only for bathing-houses.

I find I must break the thread of my narrative at this point in order to say something more about the town of Greeley, referred to in the latter part of my previous letter, Dec. 15, and to relate a pleasant little incident which happened to me there.

When our good friend Horace Greeley said, "Young man, go west," he set the example himself by going west and starting a beautiful town which still bears his name, and still does him honor, by being a strictly temperance town; for every foot of land was so deeded that the owner loses it the minute he engages in the liquor-traffic. It is interesting to know that a town *can* be started and kept sober for at least a long term of years, in just this way. The people, buildings, and every thing about the place, show the good effects of it.

At the convention we had a good joke on Mr. Theo. V. Jessup. Before he knew I was to be present he was very earnestly engaged in soliciting subscriptions for GLEANINGS, and even came to me, handed me a copy, and commenced extolling its merits. When some mutual friend came forward and introduced us, he looked embarrassed enough.

"Never mind, good friend," said I. "You needn't feel troubled. I believe this is the first time in my life that I have been urged to subscribe for my own journal."

The electric plant for lighting Salt Lake City is, I think, the largest and finest I have ever yet seen in any city. There are ten immense boilers, giving, all together, 1200 horse-power, and the dynamos for generating the electricity compose the latest and finest that are now known. A smoke - consuming apparatus is already attached to a number of the boilers, and it works so perfectly that not a ray of black smoke can be seen coming from the top of the stack. If this thing really succeeds, oh what a blessing it will be to the smoky, dingy, and blackened cities all over our land!

Utah not only claims to beat the world in variety of mineral products, but she has produced nearly 1000 bushels of potatoes to the acre, and 80 bushels of wheat. Besides producing almost every thing grown in any northern State, she is growing successfully both raisin grapes and cotton. A new beet-sugar factory is now in successful operation, and candy is shown in her confectioners' windows, made from sugar of her own production. Even though her public schools are *new*, like her electric railways, they are "getting there" all the same. Of course, I couldn't go to *all* the churches, but I attended two different Congregational, and found large and intelligent audiences. At the Y. M. C. A. Sunday afternoon I found a larger attendance than in any other city where I have traveled. I talked to them for perhaps five minutes, and I think more came to me to shake hands, when the meeting closed, than in any other place I have visited. With open saloons, of course they have intemperance; and the swearing on the streets in some parts of the city is pretty bad; but I saw notices in some of the public buildings forbidding it, and calling attention to the law in regard to it.

Dec. 9.—I am off for Washington this morning. The railroad takes its course along the Salt Lake Valley, at the foot of the mountains. In many places the number of springs at the foot of the hills is so great I am told no irrigation is needed to get immense crops. In these spring runs, a great abundance of most beautiful water-cress is found all winter long. In fact, I saw where wagonloads of it might easily be gathered. Hot springs are also found at many points. My impression is, the heat comes from chemical action rather than from volcanic fires in the interior of the earth. I find the hot spring water is all more or less charged with mineral salts. Well, the water from the melting snows on the mountains sinks into the earth; and where minerals and chemical salts are so abundant it is not strange that this water soon becomes a strong solution of something. Now, it is well known in chemistry that two solutions poured together often give out violent heat. Sulphuric acid and water is a familiar example. This will become boiling hot if mixed in the right proportion. The hot spring of Salt Lake is heavily charged with sulphur, and at the same time is very strong of common salt. If you stand to the windward side, the sulphur fumes, as they come off in the vapor, are quite unpleasant.

LETTER TO HUBER.

Well, my boy, there are several funny things true of your papa this afternoon. Let us see:

First, I am away up in the clouds—yes, almost a mile high. You see, the mountains are up in the clouds; and as we have to cross them we had to go up into the clouds too. Oh, my! but you ought to see it snow up here. You know you wanted it to snow when I left home. Second, I am away off in the State of Idaho. If you look on the map you can find it. There are a great many mountains in Idaho, and lots of pretty valleys full of horses and cattle. There are some very good horses here. Two men just jumped on their horses and bounded off through the snow and sage brush. How the horses did make the new soft snow fly with their hoofs! If it were me I should almost be afraid of getting snowed under. The sage brush is about as large as current-bushes, and so close you can just get between them. There are miles and miles of it. I think the bees might get honey from it in the summer time. We just saw a farmer out among the sage brush, living in a tent—yes, a tent in a snowstorm. Shouldn't you think he would get pretty cold?

The third thing is—what do you think? Why, to-day is the first time in my life that I was 52 years old. Funny, ain't it? that my birthday should come when I am away off up in the *clouds*, in a big *snowstorm*, out in *Idaho*.

Near McCammon, Idaho, are some strange rock formations. At first I thought a carload of railroad-ties had been stood on end for some purpose, and that they had them all tumbled every which way. Then came another such heap, then lots more. Soon I saw they were long stones, split out by Nature's hand. The queer rock all seems to be on end, and the rain and frost have split it up like blocks cut off for firewood, and the sticks just lie tumbled about. Many of them would make beautiful fence or hitching posts. In one place they are long enough for rails, or short thick telegraph-poles; but the most of them are about the length and size of ties. They stand along the track for miles, and on some of the bluffs there are just acres of them. I tried the Kodak on them; but as the train didn't stop, I am afraid the picture won't be very good.

All through Idaho we find the strange rocks I have described. A bunch of them stick up on the plain, and the pieces are scattered all about. Toward the eastern line the rocks are nearer cubical, say from two to three feet on a side; and scattered here and there over the desert waste are huge building blocks of stone, spread out, as it were, just right for the mason to go to work at. There are enough such blocks of stone for all the cities and villages Idaho will ever build.

Dec. 10.—To-day my heart is rejoiced to see a real genuine *rail fence*. After traveling for three weeks over miles and miles with no natural forests, it is not strange that I hungered for the sight of old familiar scenes. Even the horses and cattle seemed more natural, and more at home, on the other side of a rail fence. At Pleasant Valley, Oregon, I saw, also, great piles of native lumber about a sawmill. You may think strange I make so much of this; but, dear reader, what is our great United States to do for lumber when the native forests are gone? How are we to continue to build when the trees are cut down? I should say that at least nine-tenths of our land is *timberless*, and yet in many places the great effort seems to be to destroy and waste it. Since getting into Oregon I am also rejoiced to see nice patches of fruit surrounding every home. Thrifty orchards and patches of small fruit seem to go well with rail fences. Our conductor just passed through the car, exhibiting an immense apple, and a perfect beauty. He said a man just gave it him who raised it on his farm up among the hills.

Along here the rocks and cliffs are penciled with a delicate green, shading off into many tints of yellow. The effect is very fine. I think it must be owing to the minerals and chemicals dissolved by the water.

Dec. 11.—Long before daylight I was at my post by the car-window. The pine-trees are so large and so many, the daylight has been slow in getting through; but the scenery as we approach Portland is wonderful. The track runs between the Columbia River and the cliffs, and said cliffs are, some of them, almost if not quite half a mile high. Well, to add to the charm of the evergreen trees and the cliffs, beautiful waterfalls come pouring and leaping down the cliff at frequent intervals. Some of those falls almost spatter the car-windows, they are so close; and when I tell you that one of them, Multnomah, pours down *eight hundred and fifty feet* you need not be surprised that I was enraptured. Besides the falls, Nature has clothed the rocks and cliffs with beautiful green mosses and ferns, and I suppose this is the effect of the abundance of rain; for now, dear reader, we have passed the thousands of miles of rainless regions, and here in Oregon it rains both winter and summer. In fact, the abundance of rain here is one of the standing jokes. A passenger, who overheard my questions, remarked with a laugh, "Why, my friend, sometimes here with us it rains *twice* on the same day."

GLEANINGS IN BEE CULTURE
Illustrated Semi-Monthly
36 Pages 7x10
$1.00 Per Year

In the multitude of counselors there is safety.—Pr. 11:14.

While this issue is going to press we expect to take in the Michigan convention at Grand Rapids, which will be held Dec. 31 and Jan. 1.

We have given quite a long report of the North American in this issue, but by no means so full as will appear in the *American Bee Journal*, of Chicago. Thomas G. Newman & Son, publishers, will be glad to mail you sample copies.

The December *Bee-Keepers' Review* comes out with a new feature; i. e., a small portrait, in half-tone, of its regular correspondents, at the head of their articles. At conventions we like to see as well as hear the big bee-guns. Bro. Hutchinson is going to gratify that desire, so far as it can be done on paper, for a time at least.

We receive a great many kind letters, especially at this time of the year. They are of the real, homelike, chatty sort, containing words of cheer and encouragement. Such letters are always welcome, and have their influence in molding the future policy of the journal. It is impossible to answer them all, but we extend our thanks here to one and all.

It has been observed that bees will winter on honey-dew; but just how much better they would have done on sugar syrup is somewhat of an open question. Here is a little item in point, from a subscriber, Mr. E. E. Smith, of Carpenter, Ill. He writes:

> Bees wintering on honey-dew are rearing brood; but there are about twice as many dead bees in front of their hives as there are of those fed on sugar syrup.

The senior editor is not "enjoying" the best of health. He has had one or two slight relapses, the last one being at Portland, Oregon. At last reports he had left Portland for Fidalgo, Washington, the place where H. A. March, a bee-keeper and supply-dealer, holds forth. From his last letter we presume he is, ere this, on his way to a convention in Los Angeles, to be held Jan. 6 and 7. When he gets that far south, we hope that his malaria, or tendency to fever and chills, will entirely disappear.

Since our article in our last issue, we have had some inquiries as to whether the improved Hoffman frame will go in the Dovetailed hive. Why, to be sure. The real purpose of the article was to explain how the Hoffman frame had been adapted to that hive. Yes, this frame will go in any standard Langstroth hive, such as the Dovetailed. All our frames of standard size are interchangeable with any of our standard hives. The new Hoffman will go in the old-style Simplicity as well as in the latest Dovetailed hive.

No one should attempt to secure a patent on some device unless he is passably familiar with the literature relating to it—certainly not until he has read one or more of the excellent text-books. The patent-office reports show that even now patents are being granted to parties who are lamentably ignorant of the first principles of bee-keeping and of what it requires. Gleanings of to-day is *not* opposed to patents granted to practical men; but it unites with the *American Bee Journal* in protesting against this useless waste of money when the patent can be of no possible use to the owner.

We are sorry to note that la grippe is still seriously inconveniencing Thomas G. Newman & Son. It has taken a severe hold upon the junior member of the firm, confining him to his residence; and even Thomas G. himself is nearly ill. We sincerely hope for their speedy recovery to health. We have already ourselves had a mild attack of grip, influenza, or something else, but we are happy to say, at this writing, that we are on top. Dr. C. C. Miller is another one who has been suffering quite severely from the ravages of the epidemic. Although quite weak, he is still able to attend to some of his correspondence.

In one of our subscription blanks, the following words are written: "Please discontinue." No name or address was signed. As this thing is continually coming up, both for discontinuances and for renewals, accompanied with remittances, we must remind our subscribers again to please let us know who they are. We have no way but to wait for a growl, and perhaps our subscriber who desired us to discontinue may be very *much mad* because we do not obey orders; and no doubt the other fellow who has sent us a dollar for renewal will be very much put out because the date of his journal wrapper has not been changed in due time.

In another column S. T. Fish & Co. give us some startling news, to the effect that at least one large bakery has abandoned the use of extracted honey, and is now using, and will continue to use, granulated sugar, because it is so cheap, and because it is so much better. We have been a little skeptical about the low price of sugar affecting the honey-business, but perhaps we shall have to give up. If it does any thing, it will affect only the sale of the poorer grades of extracted honey. Comb honey of all kinds will hold its own just the same. The poorer and darker grades of *extracted* may suffer considerably from competition in just this way. Let us have the facts.

Remember, any subscriber may have his journal stopped at the time paid for if he will simply so order when remitting. Those who are of this class can be accommodated as well as those who are in the great majority, who do not want their journal stopped, and who will remit as soon as they can make it convenient. But all should remember that we do not allow any one to get very far in arrears before his journal is stopped, or, at least, some arrangement has been made whereby it can be continued. We are glad to state that we have no deadheads on our list. It is practically all paid up. Our advertisers get the advantage of a list of live subscribers. A deadhead list, however large, would be of no practical benefit to advertisers, but a large expense to us.

It is no doubt a fact that more *large* bee-keepers were present at the North American at Albany, and, as a natural result, a larger aggregate number of colonies were represented, than at any other bee-convention in the history of the North American. There have been larger attendances at other conventions, but never a larger number of men who count their colonies by the several hundreds. There was not only present the largest bee-keeper in the world, but a considerable number who own individually in the neighborhood of 300 or 400 colonies; and yet they are not always the ones who say and do the most in conventions; but when it comes to practical experience as touching the production of comb or extracted honey —well, they know how to "get there."

THE *American Apiculturist* for January has got things just a little mixed in regard to the Albany convention. On page 11 this sentence occurs: "The great convention has met, and was a grand blank, as will be seen by the report of its proceedings in this issue." In justice to that convention, and to Mr. Henry Alley, we gladly make an explanation. Mr. Alley says he originally wrote that the convention was a grand *success*. At the time the galley proof passed through his hands he was not sure whether it was a success or a failure, and so drew his pen across the word "success" and wrote in the margin, "Leave this blank." Mr. A. closes up his letter thus: "I'll be blast if the girl didn't insert the word *blank*. What a blunder!" Yes, Mr. Alley, it was quite a blunder. We would suggest the propriety of reading the page as well as the galley proofs. We members of the Albany convention will forgive you this time.

J. W. PORTER, of Charlottesville, Va., sends us the following letter from the Assistant Secretary of Agriculture, Edwin Willits, which will explain itself:

DEPT. OF AGRICULTURE,
WASHINGTON, D. C.
Office of Assistant Secretary.
December 7, 1891.

Mr. J. W. Porter:—Yours of the 4th instant, mailed the evening of the 5th, reached me this morning, with reference to the meeting of the North American Bee keepers' Association next year in Washington, under the auspices of the Department of Agriculture.

In answer I have to say it will be gratifying to this Department to have such meeting held here at the time indicated, and we shall be most happy to furnish your Association with every facility in our power, both as to rooms for the meeting of the association, and as to co-operation in other respects on our part. Will you please communicate this fact to the association, and oblige

Yours truly,
EDWIN WILLITS, Assistant Sec'y?

Good! We have a friend in court. Mr. Willits will be remembered as former president of the Michigan Agricultural College, and as an old friend and co-laborer of Prof. A. J. Cook. He has, therefore, more than an ordinary interest in bees and bee-keepers. We feel that we but voice the sentiment of the association when we express our thanks to him for his interest in our behalf. Mr. Porter wrote a letter to the writer, urging that the next meeting of the North American be held in Washington. When Capt. Hetherington proposed the capital of the United States, we stated the contents of Mr. P.'s letter, and fell in with the scheme at once. You know the rest.

AFTER Oliver Foster, of Mt. Vernon, Ia., secured a lower freight classification on honey, granulated, shipped in pails, we asked for a simple method of solidifying honey on short notice. The problem had been, not how to granulate it, but how to keep it from doing so; but there are certain reasons why, in some cases, it would be desirable to have the liquid product candied on short notice. Granulated honey ships more readily, and consumers are already demanding it that way for table use. No one seems to have answered our inquiry; but quite by accident we ran across the following, in the *British Bee Journal*, the editor of which translates it from a French bee-journal, *Le Bulletin Apicole:*

If the bee-keeper wishes to have his honey granulated without having to wait six or seven weeks, he can, after a week, churn it the same as is done with cream to obtain butter. Honey treated in this way granulates with a very fine grain. We have just tried this process on honey that had been extracted eight days, and in fifteen minutes the honey, in a one-pound bottle, passed from the thin liquid state to a thick syrup. Sometimes honey granulates in coarse grains, which makes purchasers think that it is adulterated. It can be melted in a water bath and then exposed to cold, when it will granulate very fine.

There, friend Foster, and everybody else who is interested, here is a plan that will probably work—that is, if you can't wait till cold weather.

"HONEY GLUCOSED BY THE HUNDREDS OF TONS."

WE have just received the following letter from M. H. Tweed, which will explain itself:

Friend Root:—I don't understand why honey-producers as an organized body do not do something toward helping on the time when this nation will have a pure-food law, such as every even half civilized nation has all over the world, excepting this. It would help the bee-keeper wonderfully. Thousands of people in cities do not use honey to any extent, not because they do not like it, but simply because they have no confidence in the article they buy, whether it be comb or extracted. Now, to show how such a law would help, take a look at the good that is done by the one in Ohio. You ask a dealer in maple syrup in Pittsburg if he has pure maple syrup. He will, if he has any Ohio syrup on hand, at once say, "Yes, this is from Ohio, and I can guarantee it pure, for they have a strict law there against the adulteration of it." It inspires confidence in the article at once—so much so that the dishonest dealer says his syrup is from Ohio, whether it be the truth or not. And another advantage would be that, instead of hundreds of tons of glucose being sold in our cities as honey, there would be that quantity of honey sold instead.

Allegheny City, Pa., Dec., 1891. M. H. TWEED.

Mr. Tweed makes a good point, providing glucose *is* sold by the hundreds of tons for honey, or mixed with extracted honey. But we can not believe that such a state of things exists; that is, we think our correspondent is misinformed. If so, we should have had some inkling of it before this. We have carefully traced down all these cases of glucosing extracted honey, and, with the exception of one case in Detroit and one in Chicago ferreted out by Mr. Newman we found that nothing but pure honey was sold. We do not deny the existence of *mistrust* on the part of consumers as to the purity of extracted honey; and this mistrust, although i may be entirely unfounded in fact, does almost the damage if the practice existed in reality. Now, let us have the facts. Let us face the lion in his den. *If* extracted honey *is* glucosed to any great extent it would be folly for bee-keepers and bee-papers to try to cover it up for fear of the bad effect on the general public. GLEANINGS is willing to invest some money in having the truth brought to light. We should be glad to have those who have positive evidence give us information, and we will see what can be done. Bee-keepers may depend upon it that they will have the hearty support of all the bee-papers and of all bee-associations, including the North American and the Bee-keepers' Union. Now, we as bee-keepers should handle this matter delicately and wisely, and be very careful about raising a false alarm *unless* there is real ground for alarm; and if glucosing does exist to any considerable extent, by all means let us go in for a pure-food law that will include honey—not only for the State of Ohio, but for every State.

Whatever we do, it should be thoroughly understood that *comb* honey can not be glucosed;

hat is, feeding the bees the stuff, would be exceedingly unprofitable. It is only the honey in the *liquid* form, that might be glucosed. If there is any of the packing houses that are guilty of this latter upon satisfactory evidence, we will see that they are thoroughly advertised and the public duly warned against them. Yes, we will go one step further, if recourses to the courts will help us.

SPECIAL NOTICES.

BURLAP ADVANCED.

The burlap we have been selling for the last year or two has been rather light, being only 7½ ounces to the yard. We have just bought a new bale, 10 ounces to the yard, and, of course, it is worth more. The price from now on will be 10 cts. a yard; 10 yds., 90 cts.; by the bale of 200 yds., 7½ cts.

Enamel cloth has again declined in price, so we are able to offer it at the old price of 20 cts. a yard, or $2.25 per piece of 12 yards.

HONEY-TUMBLERS ADVANCED.

Owing to the failure of natural gas for use in the glass-factories of Pittsburg and vicinity, the makers are obliged to advance the price, owing to the increased cost of production. The only change for the present will be on Nos. 788 and 789 tumblers, listed, page 30 of Jan. 1st catalogue. The price by the barrel will be $5.50 instead of $5.00; and for the nested, $9.70 instead of $8.70. The middle sheet of the price list was printed before we received notice of this advance.

EAGLE AUTOMATIC INDELIBLE PENCIL FOR A DIME.

We have for years been selling the Eagle automatic indelible pencil at 20c. We recently got track of a job lot of the latest style of these pencils with stop-gauge, and we bought them so low we are able to furnish them for 10c each; by mail, 2c extra. This stop gauge prevents the lead from falling out any further than you want it to write with, and the lead can be exposed for use with one hand, without the necessity of dropping it on to the other hand or on to the table, to prevent its falling out.

EARLY-ORDER DISCOUNT.

With this date the discount for early orders drops to 3 per cent. All orders received this month for goods listed on pages 10 to 29 of our new price list will be entitled to a cash discount of 3 per cent. You will have received, before you get this number, our new price list for 1892. Send in your order early, that you may have the goods made up ready for the bees when they are ready for them. Notice what Dr. Miller says in "Stray Straws," Dec. 15th number, about ordering early. It is greatly to your advantage and profit, and it greatly assists us in taking care of orders promptly in the busy season.

WINTER CARE OF HORSES AND CATTLE.

This is the title of one of our rural books written by T. B. Terry, one of our most popular and practical agricultural writers. Every one who has the care of live stock will find profit in the perusal of this little work from his hand. It is especially valuable at this season of the year when you can put its hints into practice and have the time to read it during the long winter evenings. We have made the price uniform with our other rural books—35 cts. with other goods; by mail, postpaid, 38 cts. A copy is given free for one new subscriber for GLEANINGS, with $1.00.

MAPLE SUGAR AND THE SUGAR-BUSH.

The time is near at hand when those who have maple-trees will be actively engaged in producing maple sugar and syrup; and to do so to the best advantage you can not afford to be without this valuable work, by Prof. A. J. Cook, of Michigan. It is written from actual experience in the bush in producing syrup of the finest quality. Others as well as maple-sugar makers will be interested in reading it, as any thing from the pen of Prof. Cook could not well be otherwise than interesting and profitable reading. Price 35 cts.; by mail, postpaid, 38 cts. It is given free for one new subscriber to GLEANINGS, with $1.00.

THICK-TOP BROOD-FRAMES WITH DIVIDED TOP.

In making up thick-top frames we get on many boards a piece not wide enough for a top-bar, but which will make half of one. Two of these halves make what we call a divided top-bar, which many use and prefer. In putting the frames together, a piece of foundation can be placed between the two halves, to fasten it. Many go to the expense of having top-bars split from one end nearly through to the other for the purpose of inserting the sheet of foundation when these divided tops would answer just as well, and can be furnished much cheaper. Since we began saving the pieces as above we have an accumulation of several thousand thick-top frames with these divided tops more than we have had calls for. Our regular thick-top frames sell for $1.50 per 100; but to close these out we offer them at $1.20 per 100, or $2.75 per box of 250; 500 or more at $1.00 per 100, in the flat, without comb-guides. If you want wooden comb-guides, add 10c per 100. Most of them are packed 250 in a box

SECOND-HAND FOUNDATION-MILLS.

We have the following second-hand foundation-mills in stock that some may rather have at the price than a new one. Of course, we'd rather sell you a new machine than one of these, and think, also, that it would give better satisfaction usually; still, for those who wish to make only for their own use, or in limited quantities, one of these machines will probably do you as well as a new one. We have quite an assortment to choose from, and the list will be corrected as they are sold. The earliest orders will have the best choice.

One old-style 10-inch, our make, with round cell, for medium brood foundation; has been used very little, and is as good now as a new mill at the time this was made, although not to be compared with our present make. A new mill of this size sells for $20.00. We offer this for $12.00.

One 10-inch, which answers to the same description as above, but made later, and is a little better machine. Will sell for $14.00.

One 12-inch hexagonal cell, medium or heavy brood mill of the original Washburn make, and in excellent condition. If wax is dipped the right thickness this will make excellent foundation. I believe it originally sold for $50.00. We offer it now for $17.00.

One 12-inch Dunham round-cell heavy-brood mill. This was originally used by the Dadants, and will make good foundation yet. We offer it for $18.00.

One 12-inch Dunham round-cell heavy-brood mill, in excellent condition. We took this from E. France & Son, in exchange for a new mill to make lighter foundation more feet to the pound. Their only objection was that it made foundation heavier than they wished to use. Its condition is practically as good as new, although it makes foundation about 4 feet to the pound unless the sheets are dipped thin enough to make it lighter. We offer this for $20.00, which is two-thirds the price of a new machine this size.

If any prefer we can submit samples of foundation from any of these machines before you buy. We shall be pleased to send samples from new machines if you would rather have that kind.

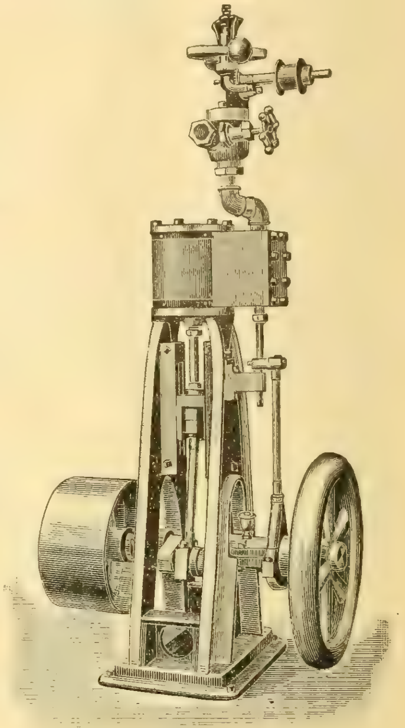
A FULL LINE OF
BEE-KEEPERS' SUPPLIES.
60-PAGE CATALOGUE.

J. M. JENKINS, WETUMPKA, ALABAMA.

ENGINES.



Yes, we build a few. We have, in connection with our large bee-plant, a first-class, well-equipped machine-shop, in which we build all kinds of bee-hive machinery, saw-mandrels, saw-tables, dovetailing-machines, foundation-mills, extractor-gearings, etc., and, when our men have nothing else to do, engines. These are upright in style, and economize floor space. They are built under the special supervision of an expert machinist of many years' experience. The rods are all of finished steel. The cross-heads and slides are of the substantial locomotive style. The cylinders are lagged with Russia iron, and are brass-bound. The boxes are babbitted, and can be easily taken up for wear. The piston-head is provided with two expansion-rings. The bright parts shine like a dollar. The governor is a Waters, substantial and reliable. We have three of these engines running in our works. One has been running two years, with excellent results. Making them, as we do, during our dull season, they are immeasurably superior to the ordinary engines of their kind, and the price is low, considering the very fine quality of the work. Price of the 2½-horse-power engine, governor and governor-belt, all ready to attach to a boiler, $75; 5 h. p., $100; 7½ h. p., 125; 10 h. p., $150. These prices are net, although we will make the usual discount for cash. If you want a thoroughly well-made engine, you can not do better than to select one of these, providing the range of power is within what you need. While we compete in quality of workmanship we can not compete in price with some of the cheap engines on the market.

A. I. ROOT, MEDINA, OHIO.

IMPORTED QUEENS.

In May and June, each	$2.00
In July and August, each	1.80
In September and October, each	1.60

Money must be sent in advance. Safe arrival guaranteed. Queens that die en route, if returned in the letter, will be replaced by mail, postpaid. No order for less than 8 queens *by express* will be accepted.

CAMERAS CHEAP.

By the death of a relative, as explained in another column, I have come in possession of two very fine photographic cameras. One of them is a Hawkeye, 4x5, with a jointed tripod. It has three dry-plate holders, and three cut-film holders. Besides this, it has a lens that cost originally $35.00, with a triplex Prosch pneumatic shutter worth $10 more. The whole outfit cost originally about $75. The camera-box has been newly finished, and looks like a brand-new instrument. It will also take a roll-holder when desired. I will place my guarantee upon the instrument as being first-class in every respect. It has a far better lens than the average Hawkeye camera. Samples of the work will be mailed upon application. Desiring to give immediate returns to the family of the deceased, I offer this camera for $35 cash. It is a bargain for some one who desires something really fine in this line. Speak quick if you want it, as it will probably be snapped up. I would, under no circumstances, let it go; but, as I have already said, I have two or three other good cameras of my own.

A 5x8 PHOTOGRAPHIC CAMERA CHEAP.

From the same source I also have a 5x8 sliding-front swing-back revolving-back camera. It has no lens. It has three dry-plate holders, tripod, carrying-case, and focusing-cloth. Its original cost was about $25. As it is second-hand, I will dispose of it for an even $10. A good lens for it can be bought for about $4.50; or for $14.50 I will include the lens. **E. R. ROOT, MEDINA, O.**

HENRY WINGERT, Loveland, Ohio.

"GRAPE CULTURE." A treatise on Grape culture, by W. E. Gould. Postpaid 25c. W. E. GOULD, VILLA RIDGE, ILL.

BOARD SIGNS AT A LOW PRICE.

We have just made a purchase of about 5000 board and cloth signs. Four of the board signs are as follows:

HONEY FOR SALE.

BEE-KEEPERS' SUPPLIES FOR SALE.

FOR RENT.

NO HUNTING OR SHOOTING ALLOWED ON THIS FARM.

They are 6 in. by 2 feet, neatly printed in black on smooth white painted boards. Price is 10 cts. each; or by mail, 25 cts. In quantities not prepaid, we will sell 3 for 25c; 6 for 40c; 12 for 75c, or a bunch of 25 for $1.25, all of one kind. We will furnish them, assorted kinds, as follows: 6 for 50c; 12 for 90c; 25 for $1.50.

We have, besides the three old signs, "Honey for Sale," "Bees and Queens for Sale," and "This Property for Sale," 4½x18 inches, and a sign—"This Property for Sale," 6x36 inches, all at 10c each; 80c for 10. All but the last is mailable at 6c extra.

A. I. Root, Medina, O.

DO YOU KNOW

that your success in securing a good crop depends almost entirely on the queen? Then **WHY** tolerate old worn-out queens, at a loss of $3 to $5 per colony in honey each year, when you can buy young, vigorous queens, of the best strain Leather-back Italians, during March and April, at $12.00 per dozen, $1.25 each? Ten per cent discount on orders booked 30 days in advance.

While we compete in quality of workmanship we can not compete in price with some of the cheap engines on the market. These engines are also connected with boilers. Write for prices.

A. I. ROOT, MEDINA, OHIO.

HONEY COLUMN.

CITY MARKETS.

MINNEAPOLIS.—*Honey.* The demand for white honey in this market is good at 18c; dark honey is slow sale at 12@13; while there is very little demand for extracted honey at 8c. There has not been a time this season when the market here has been overstocked with fancy white honey, and, in fact, as a rule, any thing desirable in the line of fancy stock is usually shipped to Chicago or other eastern markets, which is something we can not account for, as we have watched the different markets, and our market has been from 1c to 2c higher than the eastern or southern markets all the season.

Beeswax is scarcely called for at 25c.

J. A. SHEA & CO.,
Jan. 6. Minneapolis, Minn.

CINCINNATI.—*Honey.* There is no change in the honey-market. While demand is good for family use, demand from manufacturers is slower than we ever knew it to be. Cheap sugar, no doubt, is an important factor in this connection. We quote: 14@16 for best comb in the jobbing way; 5@8 for extracted on arrival.

Beeswax is in good demand, at 23@25 for good to choice yellow on arrival. Arrivals are good.

CHAS. F. MUTH & SON.
Jan. 11. Cincinnati, O.

KANSAS CITY.—*Honey.*—Demand poor. Supply large of comb, 1-lb. fancy white, 15; dark, 12. Extracted, light demand, supply light, white, 7@7½; dark, 5@6. *Beeswax*, none on the market; weather cold with light trade. HAMBLIN & BEARSS,
Dec. 21. 514 Walnut St., Kansas City, Mo.

DETROIT. *Honey.*—Comb honey continues to sell at last quotations; viz., 12@14c. Extracted, 7@8c. *Beeswax*, 26@27. M. H. HUNT,
Jan. 9. Bell Branch, Mich.

KANSAS CITY.—*Honey.*—Honey is moving rather slow. Supply ample. White comb, 14@15; dark, 9@12. Extracted, white, 7½; dark, 5@6. *Beeswax*, light supply, and demand at 23@26.

CLEMONS, MASON & CO.,
Jan. 11. Kansas City, Mo.

CHICAGO.—*Honey.*—Fancy white comb honey selling at 16; other grades, 10@14. Extracted, slow demand 6½@7½. *Beeswax*, 26.

S. T. FISH & CO.,
Jan. 7. 189 So. Water St., Chicago, Ill.

BOSTON.—*Honey.*—One-pound comb, 13@15; no 2-lb. on hand. Extracted, 7@8c. *Beeswax*, none on hand. Demand light, and supply ample.

BLAKE & RIPLEY,
Jan. 11. Boston, Mass.

CHICAGO.—*Honey.*—Honey selling fairly well for season of year, at 15@16 for white comb. Dark sells slowly, and prices are not certain, but range from 12@13. Extracted, without special change, brings 6@7@8. *Beeswax*, 27. R. A. BURNETT,
Jan. 8. 161 So. Water St., Chicago, Ill.

ST. LOUIS.—*Honey.* No change to note; inquiries light; sales few. *Beeswax*, prime, 24½.

D. G. TUTT GRO. CO.,
Jan. 9. St. Louis, Mo.

PHILADELPHIA. *Honey.*—Dull; 14@15. *Beeswax*, yellow choice, 24@25. SHOEMAKER & SCHULTZ,
Jan. 11. No. 30 S. Water St., Philadelphia, Pa.

FOR SALE.—6000 lbs. extracted honey, in 60-lb. cans.
C. H. STORDOCK, Durand, Winnebago Co., Ill.

FOR SALE CHEAP.—10 bbls. extracted honey mixed with honey-dew. Quality good. Will sell in any quantity desired. Price on application. Sample sent for a two-cent stamp.
EMIL J. BAXTER, Nauvoo, Hancock Co., Ill.

FOR SALE.—Extracted honey, basswood, mesquite, alfalfa, sage, and other varieties. Lowest prices. Correspond with us. 22-2db
S. T. FISH & CO., 189 So. Water St., Chicago, Ill.

Wants or Exchange Department.

Notices will be inserted under this head at one half our usual rates. All advertisements intended for this department must not exceed five lines, and you must SAY you want your adv't in this department, or we will not be responsible for errors. You can have the notice as many lines as you please, but all over five lines will cost you according to our regular rates. This department is intended only for bona fide exchanges. Exchanges for cash or for price lists, or notices offering articles for sale, can not be inserted under this head. For such our regular rates of 20 cts. a line will be charged, and they will be put with the regular advertisements. We can not be responsible for dissatisfaction arising from these "swaps."

Three Back Numbers of the

REVIEW

FOR 10 CENTS.

One of the numbers is that of Dec., 1891, containing 8 extra pages (36 in all) 7 half-tone portraits of leading bee-keepers, illustrated description of the best self-hiver known, choice bits of information gathered at the Chicago convention, and a most instructive and interesting discussion of "Remedies for Poor Seasons." It is the largest and best number of the REVIEW yet issued. These numbers are offered at this low price that bee-keepers may be induced to send for them, and thus become acquainted with the REVIEW; its editor knowing full well that such acquaintance will prove of mutual benefit. With the numbers will be sent a list of the special topics that have been discussed, the issues in which they appeared, and the price at which they may be obtained. The REVIEW is $1.00 a year. The book, "Advanced Bee Culture," is 50 cts. Both for $1.25. The REVIEW for 1892 will be better, brighter, and more "crispy" than ever. All new subscribers for 1892 will receive the Dec., 1891, issue, free. Address

GRADING HONEY.

J. A. GREEN PROPOSES ANOTHER SYSTEM.

I must say that I am not at all satisfied with either of the systems of grading comb honey that have been proposed. That adopted at the Northwestern convention was rather too exacting in some of its requirements, and in some respects was incomplete. I think this would be admitted by a good share of those who voted for it. At best, it was a compromise adopted with the expectation that it would be further revised before being accepted as a uniform system of grading. But while it placed the standard too high, I think the system adopted at the North American convention went to the other extreme. Any bee-keeper who is up to the times in the production of comb honey can readily select, after a good yield from white clover, linden, or any other source of white honey, a large proportion of sections that are almost, if not quite perfect in every respect—such honey, in fact, as would be graded No. 1 according to the Northwestern scale. It pays to have such a grade; and any one who understands selling honey can readily get a fancy price for it. With this grade added I would not have much fault to find with the Albany system of grading.

There are excellent reasons for the establishment of a superfine grade of honey, and there are also good reasons for using names or letters, instead of numbers, to indicate the grades, though I have always used numbers for all but the best, which I call "extra select," following with numbers 1, 2, and 3. My system of grading might be formulated about as follows, using letters advocated by the Albany committee:

EXTRA SELECT.

Light-colored honey, of good flavor; combs straight, well built out, of even thickness, and nearly uniform weight, attached to the section on all sides; all cells sealed, with white cappings, and with both comb and sections unsoiled by travel-stain or otherwise.

"A" GRADE.

Light-colored honey, of good flavor; combs straight and well built out, with cappings white, or but slightly amber-colored; one face of each comb perfect in appearance, fully sealed, except the line of cells touching the wood. The other side shall be perfect in color and sealing, or nearly so, and section not badly soiled.

"C" GRADE.

Honey of good quality. In this grade shall be placed all irregular combs, or those containing pollen, and all in which the capping is dark or considerably soiled. Sections must be nearly filled, with few or no unsealed cells.

"M" GRADE.

In this grade shall be placed all honey of inferior quality, all combs containing much pollen, or badly travel-stained, or otherwise objectionable. Sections must be at least three-fourths full, with one side well sealed.

The above is *my* system of grading—what I use in actual practice. I do not expect that it will satisfy everybody. In fact, I think we shall find it hard to establish any system that will be satisfactory in all parts of our country. This is evident when we see that the eastern men want the saffron-colored comb of the Mississippi bottoms placed in the third grade, while the men who produce it insisted at Chicago that it ought to be graded No. 1. The eastern men, too, want buckwheat honey graded by itself, though they do not seem to care about other kinds. I believe there is but little buckwheat honey produced in the West, though there are other kinds that deserve to be graded by themselves quite as much as buckwheat. As buckwheat honey is well known to the trade, it might be well enough to keep it in a grade by itself, though no doubt much honey is sold as buckwheat that was never near a buckwheat-field. But if we decide that there may be a first, second, and third grade of each kind of honey, as was voted at Chicago, we do away with one of the principal objects of grading, and open the way to almost as many disputes and differences of opinion as were possible under the old system—or lack of it.

It will be difficult to make some bee-keepers understand why their first-class honey, gathered from autumn wild flowers, should bring a lower price than another man's second or third class clover, although the commission man understands it perfectly. Would it not be better to put it in the second or third grade on the start, and so class it? Again, it is undesirable that the selling value of comb honey depend more upon its appearance than any other one quality—provided, of course, it has not an actually disagreeable taste. The kinds of honey are legion. Unless a man is familiar with all these varieties, which is something hardly possible, how is he going to be able to make a guess at the value of honey offered him from another locality? Even if he is familiar with the kind of honey offered, there is much chance for misunderstanding, for the average bee-keeper is very much at sea with regard to the sources from which his honey was gathered. Moreover, there are very few localities where any one variety of honey may be secured free from admixture. The varying nature of this admixture so changes the character of the honey, that what passes for white-clover honey in one locality may be a very different article from the white-clover honey of somewhere else.

If honey is graded according to my rules, and a sample of the honey sent in a small vial by mail, the purchaser may know just what to expect, or the commission man will be better able to inform the intending shipper what his honey will bring. J. A. GREEN.

Dayton, Ill., Jan. 8.

PRESIDENT'S ADDRESS.

READ AT THE NORTH AMERICAN BEE-KEEPERS' CONVENTION, AT ALBANY, N. Y.

The labors and experiences of another season are ended, and its lessons largely learned. A bee-keeper of my acquaintance devotes this part of the year to a careful comparison of the main points in the season's experience with those of previous years. The facts are then still fresh in mind, and the conclusions are useful. In proof that he is eminently successful in his business, I might mention his name but for fear of his modest presence with us. So we, in convention assembled, may compare our varied experiences during the season just closed, and, on doubtful points, gather wisdom more rapidly and cheaply than to work it out in our own bee-yards.

With so large a crop in one part of our country that the markets are surfeited, while much of the remaining portion is begging for choice comb honey, it may be that we shall learn a useful lesson on the distribution of our products. What are the hindrances to a better distribution of honey?

1. Our method of marketing, which hurries it off to market without waiting to learn where it is needed.

2. Freight rates are too high, and, what is worse, honey is handled carelessly by railroad men, making it difficult to reach distant markets.

After signing a release and loading and unloading his own honey, the bee-keeper is charged double the rates he ought to pay, by these servants of the people.

A recent ruling, which compelled the shipper to cover the glass, that has been used for a score of years, chiefly to secure more careful handling, is a fair sample of the treatment we receive.

This association should vigorously protest against this unwarranted interference with our rights, and a committee should be appointed to work diligently until reduced rates and better treatment are secured. We have had such a committee in our State Association, but we need a united effort throughout the country.

3. Lack of uniformity of packages and grading is a barrier to a proper distribution. What is accepted in one market is not in another. Put up the honey to meet the demands of the markets to which it is sent, has been the advice. This sounds too much like the cry of the sensational or Sunday newspaper man, who says, "We publish what the people demand," and the paper gets down lower and lower all the time. The people are often not the best judges of their needs, and often have to be educated.

Starting with the two-pound box, glassed, we have successfully met and catered to the demand for one-pound sections, glassed and unglassed, full weights and light weights, paper cartons and pasteboard boxes, wood and mica sides, thick (2-inch) boxes and thin boxes, 1⅞, 1¾ down to 1½-inch, square boxes and tall boxes, until there is the greatest diversity in packages, and it is difficult for a dealer to duplicate an order for any quality unless it is from the same consignment. The producer has wasted his substance in continual changes, and, like the sensational editor, has been but a puppet to a senseless demand.

We should adopt a stand; and if glassed honey looks better, carries better, and keeps better, why not gradually enlarge the production of this kind, and, if possible, educate the consumer to buy honey in the standard box, or "section"?

I have this year had calls for glassed honey from the West, and yearly the demand for this kind is increasing in the East.

In the reduction of duty on sugar, no bee-keeper, to my knowledge, was consulted; and fearing that, in the contemplated treaty with Spain, we might again be overlooked, I thought it my duty, as an elected representative of the bee-keeping interests of this country, to address a protest early in the year to the State Department against the free admission of honey from Cuba. A copy of the letter is here appended:

STARKVILLE, May 14, 1891.

Hon. James G. Blaine, State Department, Washington, D. C.

MR. SECRETARY:—Information reaches me that this country and Spain will probably agree upon a treaty of reciprocity. With such probabilities ahead, I desire to be informed, as representative of the bee-keeping industry, whether honey is upon the free list. If so, I wish at this early day to enter an emphatic protest against any change in the tariff.

The contemplated removal of the duty on honey in the Spanish-American treaty a few years since was met by a most emphatic protest from the 300,000 bee-keepers of the United States of America. Much better reason have they now for protesting, since the great reduction in the price of cane sugar, the chief competitor of liquid or strained honey.

The removal of the duty on foreign sugar was followed by a bounty to our domestic sugar-producers, even to the producers of maple sugar, which is chiefly an article of luxury and not a competitor of cane sugar in the manufacture as is "strained" honey. Our legislators who so kindly remembered the sugar-growers, entirely forgot the honey-producers, whose product is but sugar under another name. In the manufacture of certain products, honey is superior to sugar, although not so much superior but that we shall have to lower present prices in many cases to avoid the substitution of the inferior and cheaper article.

Now, to permit Cuban honey to enter free, and still further reduce prices, would be an act of injustice that could hardly be forgiven. In fact, it is questionable whether our industry could survive, unless it should be that limited branch of it devoted to the production of comb and liquid honey for table use. Cuba is probably the finest honey-producing country in the world, and capable of producing an immense amount of honey. So superior is it in this respect that several of our most intelligent bee-keepers have left all the advantages of their native land to engage in the production of honey there.

Our industry is still in its infancy; and while we already produce many million pounds of honey, it is capable of an expansion so great as to wholly eclipse the present production of sugar from the sugar-cane. Four contiguous counties have produced in one season over four million pounds of honey, and this represents but a fractional part of what might have been gathered.

Knowing well the genuine interest you take in the welfare of the people of your country, I am confident that you will give this subject the attention its importance deserves. Should there be any points on which you desire additional information, command me at your pleasure.

Yours, etc., P. H. ELWOOD.

President of the North American Bee-Keepers' Association, also President of the United States Honey-Producers' Exchange, and President of New York Bee-Keepers' Association.

The letter I received in reply is not at hand, but it stated that the subject should have the attention its importance seemed to demand. I am glad to say that the treaty makes no change in the present duty.

As the hand of our legislators has once been laid heavily upon us, and may be again, I suggest that a standing "watch-dog" committee on legislation be appointed. Also, if you think best, this committee may be authorized to draft a bill regulating the use of arsenical poisons on fruits and vegetables, by spraying and other processes. That bill should be in suitable form for submission to the several State Legislatures.

The Committee on Medals have completed their labors, suitable dies have been obtained, and medals stamped for distribution to affiliated societies, as called for in the constitution. Much credit is due to Mr. Thomas G. Newman, who worked on this committee with his usual vigor and ability. A few extra medals to be awarded for meritorious inventions, discoveries, and experiments, would help our society and pursuit.

The original experiments made by Professor Cook on "Fertilization by the Honey-bee," read at Washington, is worthy of a medal; but probably our awards should be conditioned on having the report first made to this society. I hope Professor Cook has continued his experiments so as to include buckwheat, as farmers have but little idea of the great benefit to be derived from the honey-bee in the fertilization of this grain.

A medal should be offered for the best essay for general distribution on "The Use of Honey in the Arts and Manufactures." When we know that a single firm of bakers within a few months bought $13,000 worth of honey to use in their business, we are led to believe that its use might be largely extended.

Manufacturers have learned that certain chemical processes take place with honey that do not with sugar.

In medicine, honey might often be substituted for syrup, to the benefit of the patient, as it is more easily digested, and in lung and throat diseases it is a valuable medicine.

Formerly it was the custom of our secretaries to prepare a copy of our proceedings for the press, or a copy from which reporters could make extracts. I advise that we return to this custom. Reporters are not familiar with bee-keeping; and while we sometimes have excellent reports, usually those published in our dailies are not creditable to either the bee-men or to the papers that publish them. I therefore ask that our secretary furnish a report for the press.

We are pleased to have with us in this meeting many representative bee-keepers who have not met with us heretofore. Mr. Frank Benton, who has nearly compassed the world in search of new varieties of bees, and to whom bee-keepers are under lasting obligations, has promised to be here.

One whom we have been accustomed to meet at our State Conventions is not here. Mr. G. H. Ashby, whom we held in high esteem for his superior qualities of head and heart, will be sadly missed on the floor of this convention.

P. H. ELWOOD.

WHAT IS HIBERNATION ?

THE BEST TEMPERATURE FOR BEE-CELLARS.

A correspondent writes, "At what temperature should bees be kept so that they will hibernate ?"

Well, that depends on what is meant by "hibernate." If that word is to be so turned from its legitimate meaning that it means getting quiet, then experience, in my case, proves that a temperature of about 42 to 46 is as near as I can come to it. If it means a sinking into that torpid state into which ants, wasps, woodchucks, and such like things go, then if such a state were possible with the bees, which I can not accept, they would require a very low temperature, and said low temperature would not only be required outside of the cluster, but the same or nearly so would obtain inside of the cluster also. That I never found the temperature lower than 60° inside of any cluster of bees, in all my experiments to ascertain the temperature of the cluster of bees in winter, even where the temperature was as low as 16° below zero outside, proves conclusively to my mind that bees never hibernate in the true sense of the word. Ants, wasps, and hornets, freeze up solid, and often stay so for months at a time, in which case they can be truly said to be hibernating; but all know that, if any colony of bees ever come to this point, even for a single day, they would never revive with the warming breath of spring.

This correspondent next asks, "Is it advisable to keep them at such a temperature that they will hibernate?" In the above he will see that, if true hibernation is meant, only loss can occur if the bees do hibernate, even if for only a short time. But if he means a state of quietude instead of hibernation, then I should say that it is advisable. The more quiet bees can be kept during winter, the better; and I find that the temperature as above given is the one in which bees are the most quiet; but under conditions different from those existing with me, a temperature varying from this might be the best. Actual observation in any case will be found of far greater value then set rules from a different locality. Try for yourself; and when you have found the temperature in which your bees are the most quiet, then stick to that till experience points out something better. Seasons sometimes vary, and you may find that the temperature of a previous winter will not work equally well the next. One thing is always to be borne in mind, which is, that bees are inclined toward a dormant state in the fall, and toward an active state in the spring. Bees go into a state of rest in October, and remain more or less in this condition, in any temperature varying from 65° above to 30 below zero, until interrupted by some disturbance, or aroused to activity by the commencement of brood-bearing, which occurs anywhere from the first of January to the first of April, in all well-regulated colonies, according to the climate they are in. After brood-bearing has commenced, more or less uneasiness will prevail from this time until the bees have the benefit of warm weather and frequent flights. A mild temperature in preserving animal vitality is to be desired, and a uniform temperature is the most congenial, the disturbance of sudden changes being avoided as much as possible.

That the reader may know a little more explicitly regarding the matter, I will say that, where a colony is wintering just as I should like, they will not be disturbed at once by the rays of light from a candle or lamp falling upon them. When I go into my bee-cellar and hold the candle so the rays of light fall upon the cluster where the bees are to be seen at the bottoms of the combs, all that is to be seen of the bees is a row of pointed abdomens standing out in all directions, all quiet and motionless, they remaining so for a moment or two, if no jar is made nor heat from the candle or my breath allowed to reach them. After a time, if the light is held steadily upon them, a few will begin to stir slowly, and, if held long enough, the whole colony will raise an uproar. When viewed from the top, by lifting the covering over them a few will slowly stir, perhaps putting out their stings and giving off a buzzing sound, as much as to say, "We wish you would go off and leave us." When in this condition, I consider that colony wintering splendidly. If, on the contrary, I am greeted with bees flying to the light as soon as I enter the cellar, and upon looking at the cluster at the bottom of the combs they are found all uneasy, crawling about and ready to fly at the light, with the hives full of restless bees clear to the ends of the frames at the top, I know that, unless this colony can be gotten quiet, they will prove of little or no value in the spring, if this happens as early in the season as the middle of February, while the colony will be much damaged if as late as the middle of March.

Another correspondent writes, wishing to know whether his cellar is suitable for bees, saying, "It is frost-proof, with a dry earthen floor, well ventilated, but there is usually stored in it all the vegetables used by the family, and frequently from 30 to 100 bushels of apples. Are these injurious to the bees? If not, I should like to store my bees in this cellar in years to come."

I should consider the cellar suitable for wintering bees, and the presence of the apples and vegetables no objection, if the temperature can be controlled between 42 and 48°. If the temperature can not be thus controlled, I should prefer to winter the bees on their summer stands. If I had been successful, or even comparatively so, in the past, I would go slow on the cellar, trying only a few in it the first year, putting in more and more each winter, according as I was successful. Decaying vegetables should not be allowed in any cellar, whether there are bees in it or not; and the bees should not be disturbed, by jarring or otherwise, when entering the cellar after any thing stored therein.

Borodino, N. Y. G. M. DOOLITTLE.

[Your statements quite agree with our observations, which we have been making of late.]

SUCCESS IN BEE-KEEPING.

ELEMENTS OF IT IN JULIUS HOFFMAN AND IN HIS METHODS.

In a former article we outlined Mr. Hoffman in his career as a bee-keeper. In this we shall endeavor to point out some of the reasons for his unparalleled success. When we claim his success to be without parallel, we qualify—i. e., we take into account his *uniformly* good results; his small outlay for labor; his extraordinary success in getting bees through the severe winters, and his large yields of honey per colony. Other bee-keepers produce greater quantities of honey, but require more bees; and the cost for labor, and the lack of general economy, leaves smaller net profits.

After Mr. Hoffman settled at Fort Plain it became a matter of great interest for us to visit him in his home apiary. As before stated, we discerned in him a bee-master of no small caliber.

We found in him a man of intense energy who is ever busy; a man thorougly educated in his calling, and well trained to execute his knowledge; a finished wood-worker who realizes the great importance of having hives, frames, section-cases, etc., made from good material, and exactly alike, so that no time be lost when time is exceedingly valuable. To these qualities may be added another, which requires that all work be done properly and in season.

His location was peculiarly fitted to bees in autumn and spring by reason of being sheltered from the west and north winds; and its sunny exposure contributed in no small degree to his exceptional success in wintering.

We saw the fact demonstrated, that, in properly shaped hives, packed with warm material, in a sheltered sunny position, bees become and remain strong much better than when conditions are different.

Mr. Hoffman's frame is about 13 inches deep and 11 inches wide, and 6 to 8 of these form a chamber, or nest, similar to the old-fashioned box hive, than which, when properly handled, no hive ever gave better results in wintering.

The *real* Hoffman frames, in use, confine the warmth at the top and for a considerable distance down the sides, and thus virtually make a box hive. Indeed, as Mr. Hoffman uses them they are warmer than the box hive, for the walls at the sides and tops of the frames are double, and nearly so at the ends, added to which he applies several thicknesses of burlap or sacking over and upon the sides of the frames.

There are some facts that amateurs can not learn too soon. One is, that bees naturally revel in warmth, and that for this reason they should be kept as warm as possible, during fall and spring, no matter where or how they are wintered. To accomplish this result, double walls and packing are needed through most or all of the year. This packing, in sunny weather, acts like a balance-wheel to a machine, i. e., the warmth accumulated during the day goes far through the night; and at all times, when sudden changes of temperature arise, the cluster need not expand or contract fast enough to disarrange it.

Another fact is, that ventilation of every description should be prevented at the top of the hive. Openings at or near the top carry away the warmth of the cluster, and allow the moisture to escape, both sure to work disastrously.

Mr. Hoffman understood these points some years before many of us had learned them, and profited by his application of the knowledge.

The following incident, that transpired during the seventies, made a deep impression on the writer's mind, and, after long meditation, led to the conclusions stated as facts, in the preceding paragraphs.

We visited Mr. Hoffman during the winter, and took a look into his cellar. As we recollect, 400 or 500 colonies were placed in it, and the temperature was rather high. The hives had no projections, and were packed in double rows, several tiers deep, leaving aisles for passing between them. As placed, they were packed like bricks, and the warmth of the different colonies was communicated to the mass, making it homogeneous. The result was, not a few of the strong colonies clustered upon the outside of the hives. Indeed, upon some hives several quarts of bees were gathered. These bees were quiet—in fact, so dormant that they scarcely moved; and, when disturbed, they turned up their stings, filling the air with the odor of poison.

We did not understand the situation then, but have since concluded that their repose was due to a perfect state of health caused by good management before they went into winter quarters.

Mr. Hoffman's hive is 16¼ inches long, hence, when filled, it holds eleven or twelve frames. Except for extracting, not over eight frames are used, hence the extra space admits two followers and gives room for lateral movement of the frames. The value of the Hoffman frame for rapid manipulation depends upon this ability to separate the frames without lifting; and herein, perhaps, as much as in any one point, lies the secret of his ability to care, almost unaided, for such large numbers of bees.

We have touched hurriedly upon the causes of Mr. Hoffman's success, and may have omitted some points. If any reader desires more light, we will gladly respond if in our power. In our next we will tell something about how we apply and use the Hoffman frame.

Canajoharie, N. Y. J. H. NELLIS.

[Mr. Hoffman is one of those bee-keepers who always meet with a fair measure of success; and this success is due in no little degree to his short-cut methods, hive, and frame. The mere fact of his handling 400 or 500 colonies, practically alone, is a powerful argument for his frame. This is right in line with President Taylor's address, published elsewhere. The reason why some bee-keepers can not make the business pay is because their methods are so laborious, requiring so much hired help that the honey costs about as much as they get for it. Such bee-keepers can never make money out of the business during poor years. When they can average 50 lbs. of comb honey, or 75 to 100 lbs. of extracted, they do fairly well. The successful bee-keeper of the future is the one who will, with a small average crop of honey, (say 25 lbs.), make a fair margin of profit; and when he has a large crop he simply has a bonanza. Now, Mr. Hoffman is one who secures his crop of honey with the greatest minimum of labor, and he is bound to make some profit, even if he has only a small yield. But he generally secures pretty good yields. Perhaps some of you may think we are "puffing" Mr. Hoffman again. We have no desire to do this, but simply to call attention to *short-cut methods*. As long as we have editorial control of this journal we are going to do all we can to cry down many of the old-fashioned long, laborious methods in honey-production.]

THE MAN WHO KNOWS IT ALL.

DZIERZON AND GUNDELACH.

Dr. John Dzierzon will reach his 81st year Jan. 16th, 1892. He is enjoying good health, is engaged in keeping bees to quite an extent, and is still one of the best if not the ablest writer on apicultural matters in his native country, Germany.

The 36th German-Austrian Bee-keepers' Association met in Luebeck, Germany, Sept. 25–28, 1891. The first one of these conventions was held in the '40's, if I am not greatly mistaken; and according to Dzierzon an invitation was also extended to the (at that time) distinguished bee-keeper Gundelach. His reply, however, to Dzierzon was that he thought he could not learn any thing more in connection with bee-keeping, and therefore should not attend. How selfish and foolish the conduct of this man appears in view of the present light of apiculture—in view of the wonderful discoveries, the many highly prized inventions! But have we reached the climax? are we on the top-round of the apicultural ladder? By no means. Much may we know; but more is to be revealed in the future; and the man who "knows it all" (?) and does not try to keep himself posted by attending conventions or reading some of the best bee-periodicals exhibits as little wisdom as Gundelach 40 or 50 years ago, when he refused to meet with the best bee-keepers of his time, when bee-literature was hardly in its infancy.

Naples, N. Y., Jan. 7. F. GREINER.

THE NEW HOFFMAN FRAME.

DR. MILLER'S SUGGESTIONS AND CRITICISMS.

Before me lies GLEANINGS for Dec. 15, open at page 956, and also one of the new frames described on that page. I have been wanting to have my say about that frame for some days, but la grippe has had its heavy hand upon me. Now, however, on this bright 28th of December I begin to feel that "Richard is himself again." And how good it does seem!

But, about that frame, Mr. Editor. First, I don't see why you should call it a "modified" Hoffman. Why, you've modified the Hoffman all out of it. The soul and essence of the Hoffman is the closing-together of the top-bars at the ends along with the closing of the end-bars at the top, so that no bee can enter from above to deposit propolis. I'm not saying that you don't accomplish the same thing as with the Hoffman, but that doesn't make it a Hoffman any more than a steam-engine is a modified horse because it does the work of a horse.

But let us examine the frame itself. That it can be used in the hives already in use, is in its favor. True, to get its full benefit the peculiar tin rabbet must go with it, but it often comes handy to mix up frames in the old hives. That tin rabbet strikes me as a good thing. It gives the advantage of allowing the frames to slide along even more readily than the Hoffman.

As to the top-bar, I must say I am just a bit skeptical about ⅝ being as good for thickness as ⅞. The little experience I have had says ⅞ is more secure against burrs and braces. It is possible that, with every thing else just right, however, that ⅝ is sufficient; and if it will do, we certainly don't want any unnecessary lumber. In any case, that bead looks like a good thing. One object in having a thick top-bar is to prevent the possibility of the least sagging; and that bead will prevent the sagging of the top-bar perhaps more than the same weight of wood added to the top-bar in any other way. There are also some other advantages in having a comb-guide, that I never thought of sufficient value to make me use a loose one; but it is well enough to have them when we can have them with no extra trouble along with the other advantages. The straight end of the top-bar will not kill bees like the Hoffman, and perhaps that will more than counterbalance the advantage of warmth in winter of the Hoffman.

The end-bar varies from the Hoffman in having one side cut to a V edge. While new it will mash fewer bees; but it is a question whether it will when it has been in use some time. That V edge leaves an angle between it and the next end-bar, and an acute angle at that, giving the bees a pressing invitation to fill it with propolis, and they will be very poor hands at the glue business if they don't promptly accept the invitation. Indeed, if they are good gluers they will be likely to fill the angle on the outside of the V edge as well as on the inside. When these two angles are filled, the frame will be worse than without the V edge, for it will be much harder to move the frames, and I suspect a good many more bees will be killed than if no V edge had been cut.

The bottom-bar squints toward a radical change. You may remember that, some time ago, I suggested that, while the best form of the frame was in an unsettled state, it might be well to consider the advisability of trying the bottom-bar as used by D. A. Jones and others. But why not go the whole figure? If I remember correctly, the bottom-bar that Jones uses is only about an eighth of inch thick laterally, and perhaps ¾ inch deep. Yours contains as much or more lumber, but its width is greater than its vertical thickness. What's a bottom-bar for, any way? For one thing it keeps the lower end of the end-bars at the proper distance apart, and I'm not so sure that it has any other use. You may say that it makes the bees build the comb down to the right place; but the bottom-bar in general use does nothing of the kind. The bottom-bar is just where we should like the lower edge of the comb to be, but the bees stop building about a quarter of an inch above the bottom-bar. I have had some combs built in frames without any bottom-bars, and they were quite satisfactory. Now, if bees will build down better to a bottom-bar ½ inch wide than they will to one ⅞ wide, will they not do still better if the bottom-bar is only ⅛ wide? Would not a bottom-bar ⅛ wide and ½ deep answer every purpose? While we are at it, let's make a sure thing of having the comb built down to the bottom-bar, with no holes between comb and bottom-bar for the queen to hide in. With such a small bottom-bar, if the bees are still inclined to leave hiding-places, the foundation might come down over the upper edge of the bottom-bar and be fastened there so as to make, probably, a sure thing. If the ½x⅜ bottom-bar is retained, would it not be a good thing to cut in it a rabbet ¼x¼ to fasten the lower edge of the foundation in?

Since you've given up the Hoffman idea of keeping the bees off the rabbets, perhaps it would not be so bad a plan to cut away all of that V edge except ¼ or ½ an inch at the upper end, and the same at the lower end. Or, it might be better still to have no V edge, and then cut away enough to make bee-space between end-bars, leaving only enough at the top and three inches lower down to hold the frames at the right distance apart. I think that would kill fewer bees than the end-bars you now have.

Now, if you think I am inclined to modify too much your modified frame, just remember that I am not yet entirely free from the influence of that great modifier, the grip.

Marengo, Ill, C. C. Miller.

[It may surprise you, doctor, if we tell you that the new Hoffman frame is more a Hoffman in its real essence of working than the one we offered last year. While we have left out one feature of the original frame, that of the widening of the ends of the top-bar, we added another, that of V-ing the end-bars, which the inventor regards as very important. You seem to have the impression that this is an addition of our own. By turning to Gleanings for July 1, 1890, page 489, you will see this V edge illustrated and described by Mr. Hoffman himself. As many may not have the back number in question, we quote Mr. H.'s words: "One of the edges of the uprights or ends of the frame, as far as they are close-fitting, should be beveled off to a little less than ⅛ of an inch, so as to meet the center of the square edge of the next frame. This will prevent the gluing and the sticking-together of the frames, also squeezing of the bees to a large extent, and allow faster working of them." You see from that this V edge is not a matter of experiment, and that your fears as to the effect of the propolis are groundless in fact. It was natural for you to think as you did; so did we. We might add, further, that the V edge requires no wedging, and this is a big point.

We used something over 500 thick-top frames last season, only ⅝ inch thick; and although most of the frames were loaded with honey there were only two or three of these frames that showed sagging of the top-bars. This sagging was so slight that it could be detected only by a straight-edge, or by sighting across the top. These would not have sagged; but the grain of the wood favored it. Practically, then, there was no sagging; but to our new thick-tops we have added a comb-guide, which will be more than the equivalent of a top-bar ¾ inch thick.

The new bottom (no, it's old) has been most heartily indorsed — in fact, so has the whole frame. We may get the bottom-bar a trifle narrower—say ⅜ square; ⅛x⅜ deep we fear would be too much of a good thing.

With regard to the whole frame, a number of the Michigan bee-keepers at their State convention said, in private conversation, they were much pleased with the modified Hoffman; in fact, we never offered any bee-keeping appliance that has been so heartily indorsed by so many letters from all parts of the country, in so short a time, as the new Hoffman frame.]

OUTDOOR WINTERING.

E. FRANCE CRITICISES DR. MILLER'S PLAN, AND ALSO DESCRIBES HIS OWN METHOD.

On page 955 Dr. C. C. Miller has an article on the above subject. He asks, "What are the objections to this plan, and what improvements are suggested?"

First objection, it is too much work, as we can accomplish the same thing with less work. His fence arrangements would be sure to catch snow-drifts if there were snow to drift. His boards standing up in front of the hives would catch rain, and lead it down to the entrance of the hives, and make trouble; and his great pile of straw over the hives would get wet, and also make a harbor for rats and mice. We have been running out-apiaries several years, and we never haul bees home to winter — no need of it. If they are properly fixed they can just as well stay on their summer stands; and as most of our out-apiaries are located in pasture-grounds where cattle, sheep, horses, and hogs all have a free run, what would become of Dr. Miller's pile of straw that he puts over his hives? Of course, if he fenced around the hives he could keep the stock away, or perhaps he could fence the whole apiary; but that is too much work; and, in fact, I'd rather have the stock run among the hives, as they keep down the grass and weeds, and the stock don't do any hurt—nothing but a blind horse. Keep the blind horse away.

Now, how am I going to improve on Mr. M.'s plan? When he has his four hives in a bunch, he is very near right; but instead of having four single hives I make the four all into one hive—make the lower story all solid together, having partitions running through the hive both ways, and have a bee-entrance on each of the four sides. Then our upper stories are made single—each one rests on one division of the lower hive. We can tier them up as high as we wish. We use two tiers of single stories, making a three-story hive during the summer and working season. When we put them into winter quarters we take off the third, or upper story; select the best frames of honey—enough to fill the second story with *full* frames of honey—I don't want the bottom frames to have too much honey in them; in fact, I don't care if they are empty combs, as the bees want empty combs below the honey, to cluster in. Then as they eat the honey out of the second story they work up; so when spring arrives the bees will be in the upper story and will commence brood-rearing up there. When they commence to store honey we put the brood below and the empty combs up; and when the colony gets strong enough we give them the third set of combs. We use an eight-frame hive—that is, in a set, 24 in all—when the third story is on.

These hives are chaff-lined all around the outside, and have a gable-roofed cover deep enough to cover one set of upper stories and still give room for straw over the bees in winter. We use a $\frac{7}{8}$-inch honey-board over the bees at all times. The cover is made in halves, hinged on top, so we can turn one half of the cover on to the other half; then we can work two of the colonies, then shut down the cover and turn up the other side, which gives us a chance to work the other two colonies.

We make a stand for the hives by driving six stakes into the ground and nailing three strips of boards across from one stake to another; make all level with a spirit-level; then set the hive on. Have the stand four or five inches from the ground. If we have four good strong colonies in one of these hives, each one has a queen and eight frames *full of honey* in the second story. If the apiary is put in a place sheltered from the wind there is not a bit of danger of winter loss. I'd rather have them out than in the cellar. I have over 100 colonies in my home yard, outside, with two good cellars—one in the center of the yard, under the shop, and one at one corner of the yard under a storehouse 20x20 feet. All the use I make of the cellars is to winter a few barrels of vinegar in the shop-cellar. The cellars were both made on purpose to winter bees in; but after trying to winter some in the cellar and some out I gave up the cellars and now winter all out.

I am aware that you will object to my large hive, as it is too big and heavy to handle. There is no occasion to handle the hive at all. When it is placed on its stand let it remain, unless you want to move it to an out-apiary or sell it. In that case three or four men will load it on a wagon.

The advantages of this large hive are, the wind won't blow it over very easily; stock won't push them over; thieves won't pick one up and go off with it, as they could a small hive. Having four colonies in one bunch they receive mutual benefit from each other during the winter; help keep each other warm, enabling us to winter safely outdoors, thereby saving the trouble of housing them. With these large hives there is no necessity of hauling an out-apiary home to winter. Just leave them on their summer stands, and save all the work and worry of moving home and back again in spring. The four-colony hive is just as good for comb honey as a single hive.

If any one has any questions to ask about these hives, sail in; I am here.

Platteville, Wis., Jan. 1. E. FRANCE.

[We have no doubt that your tenement hives work very nicely. We had one for a few years, but abandoned it finally. The only objection to them for out-apiaries is, that most of our out-yard locations are not permanent enough in their honey-flows. This is especially true in certain portions of York State, and in other localities where basswood is being cut off. As we have before explained, the inroads of civilization, large wheat-fields, and the raising of other agricultural crops, cut off clover, the original source of honey. With many of us, we want a hive that can be easily moved to a new location. For four or five years one location may be good, and then it happens that another one is better. Migratory bee-keeping is coming more and more in practice; and your large hives would be ill adapted to that kind of bee-keeping. We have no doubt, however, that they answer your requirements perfectly, as your locations are permanent as to their resources for honey.]

RECENT DEVELOPMENTS.

BY E. R. ROOT.

For some time back we have been convinced that the most satisfactory method of fastening starters is by the use of a heated plate, or tongue, so arranged as to pass under the strip of foundation, melting its edge. The tongue is then quickly withdrawn, allowing the foundation, with its melted edge, to come immediately in contact with the wood of the section. This principle is quite old, but we have been very slow to see its merits. We have made this application of the principle on various machines during the past summer; but up to quite recently we have been unable to construct one that could be sold for less than $2.50 retail. This figure we considered as almost prohibitory for the use of the machine. Besides, there were some other defects which we were not able to overcome entirely. During the last month we hit upon a plan for overcoming the defects of former machines, and at the same time making it so simple that it would not cost at retail more than $1.00, including the lamp and directions.

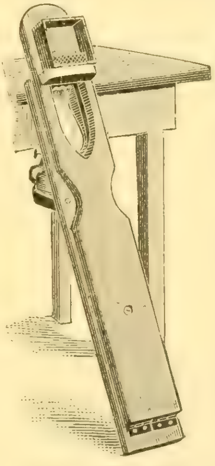

Fig. 1. THE DAISY FOUNDATION-FASTENER.

Fig. 1 shows simply two boards of unequal length, hinged together as shown in the cut. The board in the rear rests against the table at an angle, and to it is attached a lamp-shelf for holding the lamp as shown. On the top of said board is fastened a piece of steel plate, or tongue, 4 inches wide, at right angles, and long enough to project clear through a slot in the front board. The latter is made as shown, with a little shelf for holding the section. A spacing-block 3¾ square (and thick enough to center the foundation) is fastened at the right distance above the shelf, so the section can slide under it. Between the two boards is a spiral spring, and the pressure of the front board causes the two to come together at the top, making the piece of steel plate heated by the lamp below to pass under the strip of foundation resting against the spacing-block. On one side of the operator is supposed to be a pile of foundation starters; on the other side, a large empty basket for receiving sections with the starters after being attached. To put in the foundation, sit in a chair with your feet on each side of the machine. With the left hand pick up a section; set it on the little shelf, and with the right hand at the same time put a foundation starter on the spacing-block just above where the heated tongue will come through. Press slightly upon the front board or section, and this will cause the heated tongue to protrude directly under the foundation starter. Let the starter drop and come in contact with the tongue, then release the pressure, and let the foundation drop on to the section.

It will be instantly attached, and can be thrown immediately into the basket, without danger of the starter dropping out. It does not make any difference whether the day is hot or cold, or what the condition of the wax is. With this machine about 1000 starters can be put in in an hour; and it is so far ahead of any thing else we have ever seen or tried, it is with great pleasure that we present it to the bee-keeping public.

WIRING FRAMES, AND FASTENING FRAMES TO TOP-BARS.

For some time back the Dadants have told the bee-keeping public in their excellent work, the Revised Langstroth, the best and most satisfactory way of wiring frames and fastening foundation to the top-bar. The writer personally has been somewhat interested in the plan, but never "got around" to put it into execution. From the test we made last summer we were convinced that the *horizontal* wiring as described by the Dadants was the simplest, and most satisfactory in its results, of any plan we have tried, and you know we have tried a good many. We once thought that foundation would buckle or bulge out between the horizontal wires; but by observing the precaution of not drawing the wires tight—just tight enough to take up the slack, there will be no trouble with buckling, even with the thinnest foundation. Our experience, as well as that of the most practical and extensive bee-keepers who have tried it, say that it is so; and the bee-keeper who *won't* try it is not doing himself justice.

For the L. frame we place the wires 2½ inches apart. This makes three wires, the first wire being 2½ inches from the top-bar, and the bottom wire ⅝ inch from the bottom-bar. Of course, the end-bars should be pierced in the first place by your supply-dealer; but if they are not, you can do it with a brad-awl very quickly if you use a little ingenuity. The wires are imbedded in the regular way, with the foundation-imbedder. While the Carlin tool works very nicely, it is by no means equal to a spur-wheel such as is shown in the accompanying cut.

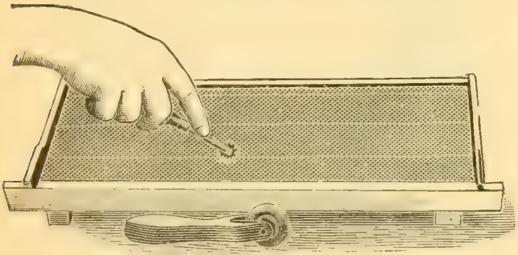

Fig. 2. IMBEDDING FOUNDATION.

The cut above shows the horizontal wiring such as we have described, and how the wire is pressed into the foundation. The special feature of this little notched-wheel tool over the other is, that you do not have to lift it up to take a "fresh bite;" and another thing, it will run clear up to the end-bars, while with the other tool you must "back up," as it were, making an extra operation. We gave our girls who imbed foundation for us the choice of the two implements. As we had only one of these wheel tools, they almost quarreled, sometimes, about it, especially when they were imbedding by *piece work.*

HOW TO FASTEN FOUNDATION TO THE TOP-BAR.

Our new top-bar, while it is a most perfect comb-guide, is especially adapted to fastening foundation.

Formerly we have rubbed the foundation on the comb-guide—an operation which, while satisfactory in its results, was too slow. We finally devised the tool after the Hambaugh device, as described in Dadant's book. As shown in Figs. 2 and 3, it is simply a wooden handle notched out to receive a wooden wheel 1½ inches in diameter. The edge of this wheel is rounding, and ¼ inch thick. The operation of fastening foundation is simply to run the wheel along the edge of the foundation against the comb-guide. A couple of "sweeps" make the fastening so perfect that the foundation will tear off before it will pull off. Another thing, it does not matter whether the wax is cold or warm; and all that is necessary is to dip the wheel into water occasionally, to prevent sticking to the foundation. This is really copied after the Hambaugh device. We hesitated to christen it by that name, as it might make confusion with a different model of the same device originally designed by "the gentleman from Illinois."

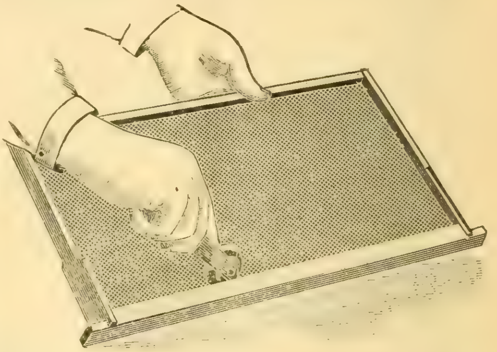

Fig. 3. FASTENING FOUNDATION TO THE NEW TOP-BAR.

IMPROVEMENTS IN EXTRACTORS.

Within the last two or three months Mr. Washburn, the foreman of the machine-shop, that expert mechanic who first perfected foundation-rolls, has been asked to turn his attention to the construction of extractors. We have had frequent complaints of the old Novice gearing being too light, and accordingly Mr. Washburn was asked to make drawings for a cast-iron arm to reach clear across the can. We further stipulated in our instructions that the gearing was to have the handle at the outer edge of the can, so that there will be as little as possible in the way of putting in and withdrawing the combs in the baskets. The following cut shows the result.

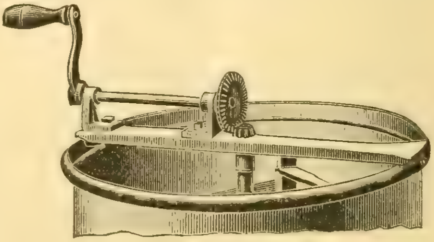

Fig. 4. THE NEW HORIZONTAL EXTRACTOR-GEARING.

This gearing, as well as the cross-arm, is old in principle; but it is new in connection with the Novice extractor. We have been corresponding, as well as asking the opinion, at conventions, of large extracted-honey men, as to the kind of gearing they preferred; and the decision has been uniformly for one like the one shown in the cut, Fig. 4. "Whatever you do," they said, "don't make your gearing too weak. Err on the side of making it too strong, if anything, even to the appearance of being clumsy." The last gear we made is strong, but not clumsy; and to appreciate the difference one has only to try the two kinds. It costs a little more, and for the present we shall have to charge a little more; and those who wish this gearing will have to specify it in their orders.

REVERSIBLE EXTRACTORS.

The one great trouble with reversible extractors has been that they are very expensive, and the can so large as to forbid their going through an ordinary door, and, in general, large and unwieldy to handle. Mr. Washburn, at our suggestion, has finally perfected a reversible two-frame machine that will go inside of a 20-inch can — that is, one of the small standard sizes of cans. Furthermore, we have dispensed with the center-shaft and the chain that is objectionable in other extractors of the kind. While the extractor is not automatic, it is next thing to it. The minute the machine stops, by twisting a couple of thumb-screws, not shown in the cut, it will reverse the comb-pockets in the fraction of a second, and the machine set a-spinning, with the other surfaces of the combs exposed to the can. We have tested the machine in actual extracting, and know that it will work. We have also sent one to be tested by some of the large honey-producers of York State, and we are at present awaiting suggestions and criticisms. This is the same principle that was recommended and indorsed about two years ago, by that extensive California bee-keeper, J. F. McIntyre, of Fillmore, Cal.

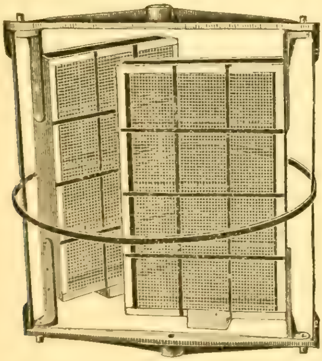

Fig. 5. THE COWAN RAPID REVERSIBLE EXTRACTOR-BASKET.

We have christened the machine the "Cowan Rapid" because it is a copy, with some of our own improvements, from a machine invented by Thomas Wm. Cowan, editor of the *British Bee Journal*. The cut shows how the baskets are hinged on the opposite sides of the frame. A couple of convenient *thumb-screws*, attached to the top hinges, will cause reversing to be done in as short a time as if the machine were automatic, after a little practice. The ring encompassing the frame is to stop the baskets as they reverse, and dispenses with the annoyance of hitching and catching of the chains. The whole inside of the framework is made very strong; and the fact that Mr. Washburn has supervised its construction is a guarantee to that effect. This whole extractor complete, in a japanned can, sells for little more than the non-reversing machines.

We may say here, that W. Z. Hutchinson, of the *Bee-keepers' Review*, examined it very critically when he was at our place; and he made the statement that, if he were to purchase an extractor, this would be the one he would select.

TUNISIAN OR PUNIC BEES WHICH?

ARE THEY ONE AND THE SAME?

At the November meeting of the Entomological Society, Mr. W. F. Kirby exhibited a series of a dark-colored form of *Apis* reared by Mr. J. Hewitt from bees said to be imported from Tunis. We have had an opportunity of seeing these bees, and, so far as we can judge from dried specimens, they are no other than ordinary Tunisian bees, which we have already described as being similar to those from Algeria and Morocco, and not a new species at all. Mr. Kirby stated that Mr. Hewitt proposed to call them "Punic" bees, and he stated that they were different from the ordinary Tunisian bees. We fail to see any difference, and there will be some difficulty in persuading entomologists to adopt a new name for well-known bees. We were also told that these bees would not sting, which made us smile, more especially as we remembered what Mr. Benton had said about them. Here are his own words when he wrote from Tunis, March 20, 1885, "They are also active, energetic workers, but, unlike Cyprians and Syrians, they are liable at times to fly at one and sting him when he approaches the apiary, and yet does not molest the hives."

There is a great deal we could say about Tunisian bees; about the "Kassartyr" apiary of forty hives; about a French gentleman (whose name, for obvious reasons, we at present withhold), whose apiary is not quite on the border of the Sahara desert, who exports Tunisian bees to England, and upon whom (if not in Paris), amongst other bee-keepers we intend to call when we go to Tunis for the purpose of ascertaining why Tunisian bees, which are of the same race as those of Algeria and Morocco, and, we may add, of the Balearic Islands, sometimes show yellow, which the bees of the last three places do not. Of course, we have our own theory on this matter, but we wish to verify it on the spot by personal observation. We hope, also, before long, to be able to show specimens of these bees from all the above places at a meeting of the Entomological Society, and also of the Linnean Society. We were much amused when Mr. Kirby told us that the importer wished these classified as *Apis niger*. As they are already classified as *Apis mellifica*, it is not likely that the name will be changed for Tunisian bees, which are only a variety of this species.—*British Bee-Journal*, Dec. 17, 1891.

BURR-COMBS AND WIDE TOP-BARS.

FROM ONE OF THE PIONEERS ON THE NON-BURR-COMB QUESTION.

The above topic has been discussed many times in GLEANINGS during the past two or three years; and every time I see an article on the subject I am tempted to rewrite an article I wrote a few years ago for GLEANINGS, which was refused publication, and returned for the reason (as I suppose) that the idea of wide top-bars was not *then* popular. Now that wide top-bars are popular I hardly think this article will be refused. Several years ago some one asked through GLEANINGS what was the cause of so many burr-combs in his hives; and A. I. Root replied that he could not tell; thereupon I wrote an article in answer to the question, which was, in substance, as follows:

The reason was, on account of narrow top-bars. I gave, for instance and proof, that, if our top-bars were very narrow, say ½ inch or less, that the bees would of necessity extend their cells out past them, and, as a natural consequence, would build the combs upward on each side of the top-bar, and fasten them to the section-case; therefore I argued that wide top-bars would be the remedy.

Now, it is useless to say that I am pleased to note that the narrow top-bar has proved, as I said several years ago, to be the trouble. Some lay great stress on *thick* top-bars; but I think that, after it is thick enough to prevent sagging, any greater thickness avails nothing. As to the width of the top-bar, it depends on how far the combs are spaced from center to center. If spaced 1⅜, the top-bar will do 1$\frac{1}{16}$ in. wide; but if spaced 1½, they should be not less than 1⅛ inches wide. I think the new thick top-bar, as you now make it with molded comb-guide, is a great improvement, as also your improved Hoffman frame.

It is encouraging to see the improvements that have come up in the last few years. I have often been amused to see the younger Root taking up with the improvements of the times, and breaking off from many of the appliances that the older Root has hung on to so tenaciously for these many years; but as improvements come up we *must* take advantage of them or we shall be left in the race. W. S. VANDRUFF.

Waynesburg, Pa., Jan. 4.

[Even the younger Root, while disposed to accept new things, has opposed some ideas that, afterward, he was very glad to accept. Some of us require more proof than others.]

THOS. G. NEWMAN AND DR. MILLER ON ESSAYS.

WITH A GOOD PRESIDENT THEY ARE NOT NEEDED FOR CONVENTIONS.

Essays at conventions are sometimes quite unnecessary, as they were at the late convention at Chicago. At some conventions, we know that they are not only desirable, but very necessary. Dr. Miller, in the last GLEANINGS, in his usual happy vein, writes thus on this subject:

> When Newman, of the *American Bee Journal*, changes his mind, he makes no bones of saying so. Formerly he argued that essays at a convention were essential. Now he says, in the most unreserved manner: "The Northwestern was a convention without essays, and it was a charming success. There was no want of subject-matter to discuss, and no lack of enthusiasm."

It was only the doctor's extreme modesty which prevented him from quoting the whole item. The rest of it, on page 709, reads thus: "With such a president as Dr. Miller, no essays or programs are ever needed." And that is the key to the situation.

If the president is thoroughly capable of being the program himself—if he is "full and running over" with subject-matter—if he is so well acquainted with the members as to grasp instantly their individual opinions and views, so as to call out a full discussion, by continually suggesting that Mr. So-and-so "holds a different view, and we should like to hear from him on the subject," or words to that effect—then neither program nor essay has any place in such a meeting.

President Miller is so much at home as chairman of a bee-keepers' assembly that he knows how long to carry on a discussion—in what channel to direct it, when to stop, so as not to weary the members, and has a happy manner of saying so—that he is a whole convention in himself, including essays and program.

The doctor's extreme modesty led him into this "exposure," and he must not now complain. So far as the item in GLEANINGS was concerned, it did not represent us correctly without the last sentence—and so it was necessary for us to correct it.

Dr. J. W. Vance wisely remarks thus in the Wisconsin *Farmer*, on this subject:

> The *American Bee Journal* says there were no essays read at the recent meeting of the Northwestern Bee-keepers' Association, and yet there was no lack of subject-matter for discussion, nor want of enthusiasm. The convention was an eminent success. The editor adds: "With such a president as Dr. Miller, no essays or programs are needed."
>
> I am inclined to think too many or too lengthy essays are not good for our annual meetings. Generally we have had good essays, but the greatest interest of the meeting has centered upon the dicussions, which often had to be cut short when at the most interesting point.

Essays should lead only far enough to suggest points for discussion, and in that way they are very good. But if they overpower and crowd out discussion, they are worse than useless.—*American Bee Journal*.

ABSORBENTS OR NON-ABSORBENTS FOR OUTDOOR PACKING FOR WINTER.

WHO WAS THE FIRST TO PROPOSE LETTING THE BEES SEAL THE COVERS TIGHT FOR WINTER?

Friend Root:—I have been much interested in reading your review of G. R. Pierce's book, "The Winter Problem in Bee-keeping," and your experiments along this line. I beg to call your attention to my articles in the *American Bee-keeper*, which were commenced in the *Bee World*. On page 164, *American Bee-keeper* for November, you will see that I there used almost the identical ideas you have expressed. This was before you or friend Pierce either ever made public the idea of having a board *sealed down* over the bees. Please give me credit in your next issue for being the first to publish this idea. I also said that the pollen theory cut no figure in my locality. To save you the trouble of hunting up the item I clip from the *Bee World* the same item, with the points to which I beg your attention specially marked. This article first appeared in the *Bee World* for July, 1891. Give credit to whom it is due. It was original with me.

T. K. MASSIE.

Concord Church, W. Va., Dec. 23.

We have made an extract from the article referred to in the *American Bee-keeper*, which is as follows:

> The box-hive brethren "rob" their bees in June, or early part of July. The head is then nailed on tight and daubed around with mortar. The bees also go "chinking" up the cracks and crevices on the inside with propolis, so that, by the time cold weather comes on, the hives are just about air-tight, and upward ventilation is an impossibility. The sealing of propolis is not broken in the fall to remove pollen, or for any other purpose. The bees, as previously stated, come out strong and healthy in the spring. From these facts I have drawn the conclusion that the pollen theory and upward ventilation cut no figure in the winter problem in my locality. It may be said that the box hives have the larger entrance, and therefore more ventilation at the bottom. True; but this is easy to remedy, and it seems to me Dr. Tinker is a long step in advance in this respect by this arrangement for ventilating his hives through the bottom of his winter case.

Now, if we place a thin board down solid on the top-bars of our brood-frames early enough in the fall for the bees to glue up the crevices, and thus prevent all air currents from passing up through our hives, we again get even with our box-hive brethren; and where we prevent all radiation of heat is by placing a cushion on top of this board the same as we do the side; and, further, in spring and early summer when we give our bees just the ventilation required by raising this board we are another long step ahead of them. This board should be thin, so that it will warm through quickly when we remove the cushion, and let the sun's rays strike it. It is just as good, or better, an absorbent of moisture than the Hill device, or sticks and chaff cushion.

[Yes, that is quite in line with our experiments. You are not the first one to make public this matter of sealed covers under packing. This is a very old, old idea, and was made public years ago. We have not taken time to look over the files of the bee-journals, but we call to mind Mr. Francis Danzenbaker, now of Washington, D. C., who wrote an article some two or three years ago, emphasizing this point very strongly. After all, it does not matter very much as to who first made the matter public. The real question should be, "Are absorbents a detriment? and if so, is a sealed cover, or a board over the frames, better?" So far we agree with you that it is. Mr. Pierce, you will remember, has been working on this same idea for the last four or five years. Probably this will call forth information as to who made the matter public some years ago. There may be a satisfaction in knowing, even if there is no practical importance attached to it.]

* * *

RAMBLE NO. 51.

AT DOWAGIAC.

My friends, did you ever see an emery wheel at work? Of course, you have; and you have seen what a smart wheel it is too. An emery wheel at work means business. Mark a point back on your piece of hard steel, and apply pressure, and the wheel soon gets there. To get there is second nature to an emery wheel; and what a reckless way it has of showering stars, comets, and whole constellations around it! how the streams of fire scintillate, glow, and snap! and how we admire them!

We have to go to the material world sometimes for a comparison for certain men we meet. Should you meet the man I met in Dowagiac, Mich., and call him a sitting hen, everybody would laugh at the preposterous comparison. Some men are called foxy; but this man is not, for he is not after things that do not belong to him; neither is he a snake in the grass. All know just where he stands; so the brilliant scintillations of the emery wheel remind me of the remark of a prominent bee-keeper in Michigan, that I would meet the smartest bee-keeper in America in Dowagiac. My comparison is correct, and James Heddon is the man. If his inventions, his writings, and the discussions and stir caused by them during the past few years, have not been a sort of pyrotechnic display, then our comparison is vain; and whatever may be said of the man or his methods, there has certainly been an advance in practical bee culture since the display commenced.

I found Mr. Heddon a prominent factor in the pretty little town of Dowagiac. As a live editor of the leading newspaper of the county he has a deep interest in the welfare and development of the town. It was to this office I wended my way after alighting from the train, finding the office occupied only by writing-tables, type-writers, and a profusion of books and papers. I pushed on to a rear room, and was met by a large, well-regulated, benevolent-looking man, with sandy hair and beard, who informed me that Mr. Heddon was not only out, but out of town, but would soon return. This was encouraging news; and after a lunch at the hotel I found Mr. Heddon, or, rather, he found the Rambler, and in a short time thereafter we were doing the town behind a horse that was 75 per cent faster than that "slow poke" of E. R. Root's. We were bowling along over the level roads, taking in the beauties of the town, when a young man was overtaken and invited to ride. This was Mr. Heddon's apiarist, Mr. McNiel. The young man looked lonesome on the rear seat alone, and another man was called in to keep him company; and it was that benevolent-looking man I first saw in the printing-office. The introduction given here in the wagon awakened a lively interest in my thoughts toward the man. It was Mr. Herbert A. Burch. Mr. Burch a few years ago, as will be remembered by the older bee-keepers, was an apiarist, and an instructive writer upon the various phases of bee culture. Winter losses, confidence in those unworthy of it, and perhaps mistakes in business calculations, threw a cloud over his name, and he retired from the business. That he is now Mr. Heddon's trusted manager of the Dowagiac *Times*, and has done all he could to straighten out the tangles of the past, the Rambler believes should be known; and I offer this as a slight tribute to a man who may have suffered silently, but who deserves the sympathy of the many who have made mistakes and had misfortunes.

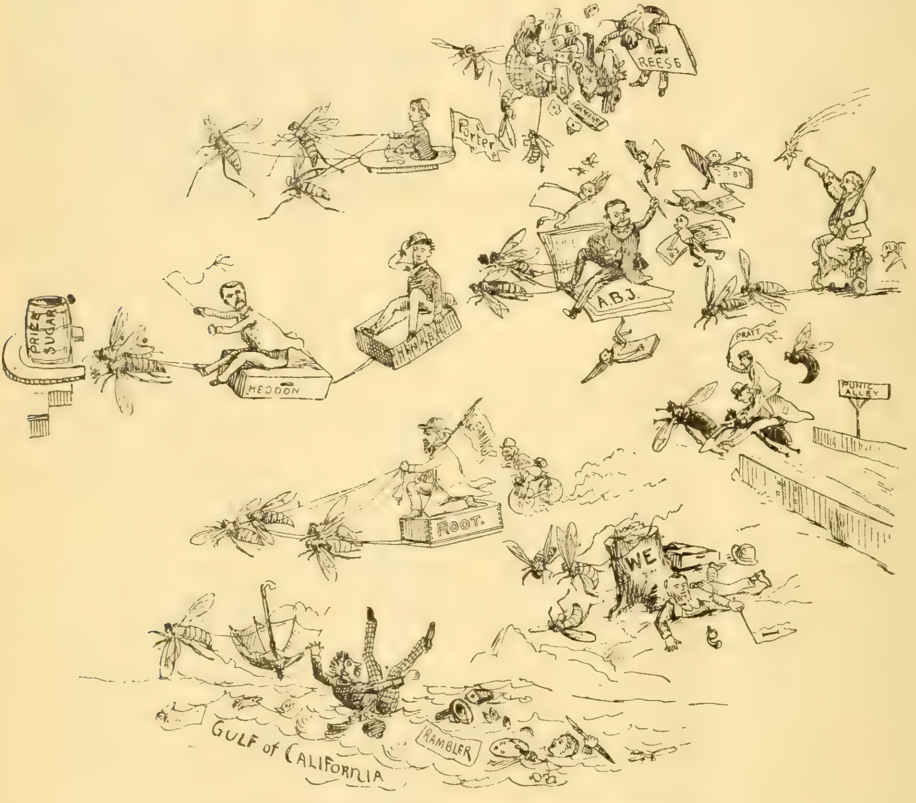
THE RAMBLER AND HIS EMERY WHEEL.

In the evening our party was increased by the presence of Mr. Stolley, a bee-keeper, and Mr. H.'s two sons; and under the brilliant electric lights we listened to the past, present, and future conditions and methods of bee culture.

Mr. Heddon is rapid in the use of language, positive in expression, and emphasizes his words by muscular action. A rocking-chair is made for ease and comfort; it was probably a comfort to Mr. H., but the chair had a hard time of it. It was well made, however, and stood the racket. Mr. H. is a universal genius. Among other trades he has been a shoemaker, tinsmith, blacksmith, carpenter, teacher in dancing, and Sunday-school superintendent. The latter occupation must have occupied attention several years ago. I judge so from the nature of the story he told us about the Devil and the minister.

Mr. H. is now editor of the Dowagiac *Times*, a clean-cut political paper of Democratic proclivities.

Still, for the money invested, time and expense and work, the apiary was the best paying business in which Mr. H. had ever engaged. My call was made in the height of the basswood season, and that day the bees were booming on it. During the night, heavy thunder showers prevailed. The electric lights of the street were set to dancing by the vivid discharges above; and when the day finally dawned, a cool north wind prevailed. The horse was called to duty again, and his fleet feet covered several miles ere we returned. Several basswood groves were passed. The north wind was swaying the pendent blossoms to and fro, but not a honey-bee was at work. "This means $75 out of my pocket to-day, and every day this lasts," anxiously said my friend.



HIVE-HOBBY RIDING: THE RACE FOR SUPREMACY.

Many clumps of pleurisy were pointed out here and there in the fields; and that great northern honey-plant, epilobium, had put in an appearance further north, and given Mr. H. an enthusiastic hope of its further rapid advance.

The home yard in the outskirts of the town contained about 200 colonies of bees, with a commodious honey-house upon one side, and all surrounded by a high and tight board fence. Every thing in the interior of house and yard was neat and tidy. A large double-geared Stanley honey-extractor was on duty. One very convenient arrangement was a large tank, into which water could be drawn, cans of honey placed, and all heated from a stove in the cellar. A large amount of candied honey can be quickly and safely prepared for market. The Rambler would have been pleased to present with this a photo of the apiary; but our camera was at the hotel, and Mr. H. has never had a photo taken, as there is no place, according to his mind, to get a good view of it.

Upon entering the apiary one becomes aware of the fact that but few of the new divisible brood-chamber hives are used here. Mr. Heddon, being an economical man, he will not destroy his good L. hives, but prefers to replace them gradually, and run his out-apiaries with the new hive. The idea has never been conveyed that any more honey can be obtained in the new hive than in any other standard hive, but that it can be obtained easier, and with less manipulation. The Rambler has used the H. hive to some extent, and wishes here to summarize some of the good points. While I do not insist upon a divisible brood-chamber, I still find many good points in it that, after much questioning in my own mind, lead me to prefer it. Contraction can be accomplished in a moment, and the whole force confined to one case. Expansion can be as quickly accomplished, and a colony built up rapidly, and not a frame removed. If it is desired to increase the number of swarms early, the shallow cases accomplish it with the least amount of labor. The queen-excluding honey-board has come to stay, and it can be used to greater advantage, and to a wider extent, than upon any other hive. The latest improvement before the fraternity, and the full import of which is not yet fully appreciated is the Porter bee-escape (which is really the only good escape. This can be used most successfully with the shallow case, and with no other. With this case the hot, disagreeable work of brushing bees from the combs is at an end; also the exposure of dripping combs when returned to the hive. And now the only thing in the way of enabling one man to extract from double the number of colonies he now does is an uncapping-machine and a cheap motor; and let me tell you, friends, electricity is going to do it.

The L. frame is a good enough frame in the brood-chamber for probably a great majority of bee-keepers; but the tendency of the times is to have every thing half story above it. There are other favorable points in the shallow hive in relation to feeding, wintering, and moving, and the above points were arrived at among the hills of New York, in actual work with over a hundred booming colonies. When the prejudice and factional feeling that has been aroused by perhaps a too acrimonious discussion subsides, the divisible brood-chamber will occupy a more prominent place in the broad field of apicultural pursuit. The race for supremacy is for the most deserving; and in the hours of the night, and while in the elegant home of Mr. Heddon, and while the thunders were rolling and the lightning flashing, our disturbed slumbers saw the grand race for the prize. "Who will win?" is the query of the

RAMBLER.

[The junior editor has never had the pleasure of meeting Mr. Heddon personally, although we have talked back and forth pretty freely over the typewriter. We expected to meet him at the Michigan State convention at Grand Rapids, but for some reason or other our Dowagiac friend did not make his appearance. It is no doubt true, that Mr. Heddon has contributed to the world several useful inventions. He has a keen perception of what is useful and practical for the apiary.

Well, now, about that dream. You have put Heddon in the lead, but we hope he is not after the sugar-barrel only. It is "Success in Bee Culture" that he is after, not sugar. We suppose that is Dr. Tinker who has hitched his hive to Mr. Heddon's. Possibly Tinker may object to that impersonation; if so, let him score the Rambler. That man Porter is getting there too; and the other fellows who would be his rivals seem to be utterly demoralized in the race. And there comes Bro. Newman, of the *American Bee Journal*. He seems to be combatting successfully some imps which we suppose to be newspaper canards. The one he has slain is probably the wily Wiley of artificial-comb notoriety. We wonder whether some of those imps are not grip seeds floating around seeking a lodging-place. If so, we hope Bro. Newman will make them all bite the dust. Bro. Doolittle is riding on a log skep as an emblem of nature, and carrying along his two hobbies, his telescope and rifle. Hello, there is Alley riding Punic bees up Punic Alley for his hobby; and E. L. Pratt seems to be pretty well on top. Who is that gentleman by the stump? Why, that must be Dr. C. C. Miller. In his onward flight he must have encountered, with his personal pronoun *I*, the editorial *we* in the shape of a snag or stump. How could you, Rambler? You have gone and cartooned both the senior and junior editor; and, worse than all, you have got *Heddon's* hive nearer the goal than the Dovetailed. We suppose the little fellow behind, with glasses, on the Safety bicycle, must be the chap who went through York State, and came back home crazy on fixed distances.

There, just as we expected. The onward rush has been so great that the Rambler has finally landed in the Gulf of California; and our friend the artist is barely able to keep his head above water. Well, dreams are deceptive; but sometimes they come "awfully near" picturing truth.]

MICHIGAN STATE BEE-KEEPERS' CONVENTION AT GRAND RAPIDS.

NOTES BY ERNEST R. ROOT.

I arrived at Grand Rapids on the morning of the 31st of December. After registering at the hotel I inquired where the bee-keepers' convention-room was. As I did so, somebody who looked very much like the Rambler turned and inquired whether I was Ernest. In the language of the Rambler, we "exchanged our identity." Instead of being the California man, however, it was none other than a bee-keeper whose acquaintance I had long desired to make—George E. Hilton, of Fremont, Mich. Mr. Hilton explained that only a few had come, and that most of the trains on which the bee-keepers would come arrived after one o'clock. After making the acquaintance of the few who were present, we adjourned to Mr. Hilton's room, where we had one of those delightful, informal conventions.

It was not expected that the attendance would be very large, or even up to what it had been formerly. Michigan bee-keepers had passed through another very poor honey season. Very few indeed there were who could report an average yield of more than 10 lbs. per colony. But there was a fair attendance at the opening of the convention, in the afternoon. After the transaction of a little business we listened to President Taylor's address. I was prepared to take notes in the usual way; but as I listened I became more and more convinced that the address was so valuable, and so vital to the interests of all bee-keepers, that it would be an aggravation for you to read only a brief *resume* of it. I accordingly stopped taking notes, and at recess requested a copy of the address in full, which I am glad to present and recommend to the careful perusal of every bee-keeper. Mr. Taylor prefaced the reading of his address by stating that he had chosen for his subject,

ECONOMY IN HONEY PRODUCTION.

Another year has come, bestowing its blessings where it listed, and is gone; and whether it has favored us as we had hoped and desired or not, we may well look, and in no complaining spirit, to discover, if we may, by what rule its largesses have been bestowed, and why our expectations have not been met. To the country at large, its bounties have been unexampled; but to those who pursue that vocation which this convention is met to promote, they have been, we will pretty generally agree, in one point at least, rather meager. But are we altogether right in our estimate? Are we not too much given to cultivating a feeling of disappointment, that we do not get a heavy crop, rather than to accepting an average crop with gratification, or to making the most of a small crop? Relatively we have, of course, had a bad year. Some have even had no surplus at all; but, on the average, has the year been necessarily an unprofitable one? I say *necessarily*, because sometimes one has notions of the profitable character of the venture he is about to engage in so elevated that he wastes sufficient to make a fair profit.

Once, many years ago, a craze for the production of hops took possession of the farmers in a certain locality near where I lived. Prices were high; the crop, in their estimation, certain, and so they were impressed with the certainty that inevitable wealth must fall to every one engaging in hop-raising. Then, naturally, the absolute certainty of coming wealth ushered in a feeling that it was already in possession. At furthest the gold was only over the fence, in the soil of the hop-field, and a little plowing and harrowing in the spring would secure it; so they were already wealthy, and acted on the assumption. No effort was made to secure a line of retreat. Victory was sure. Extravagance in the building of hop-houses, in laying in supplies for the pickers, and for the handling, weighing, drying, and packing of the hops, ruled the hour. But the storm came. Insects infested the hops; the quantity, quality, and price were all lessened, and bankruptcy overtook nearly all of them. The same thing is illustrated by numerous instances in the pine-lumber business. High expectations obscured the necessity of care and economy, and waste kicked the profits out of doors, and let in disappointment and failure.

Ruminating upon these things in connection with the business of honey-production, the idea suggested itself that perhaps our notions of the status of bee-keeping with respect to profits and necessary expenses need readjusting, and that the present series of bad years would be a good time to consider the subject.

It may be, I thought, that we are risking a chance of failure by encouraging fanciful prospects of success which are much too highly colored, so that we become content to calculate that, though by the spending of time in the useless manipulation of the bees, and by the purchase of elaborate lines of machinery and supplies we make the cost of comb honey 12 or 14 cents, we may yet be sure of a crop large enough so that the difference between those figures and the selling price will yield a good profit. I do not question the prospect of profits in fair seasons, with good management; but I wish to call attention to the danger of putting too much reliance on the profits, trusting that they will carry us through, no matter what the seasons are or to what a high point we run expenses. If one practices proper economy, and thereby keeps expenses down to the lowest reasonable point, he has still no bonanza, to be sure, but a safe, comfortable business. The criterion of expenses should be actual needs—not what it may be supposed the business will bear. If we make this latter the test, as the majority are greatly inclined to do, we are all sufficiently optimistic to fall into the fatal error of putting the average yearly production too high, and, as a consequence, to encounter failure in the end.

Mr. G. M. Doolittle has said, that, if labor and capital get their due reward, the cost of comb honey is 13 cents per pound. It would be interesting to know how he arrived at his conclusion. Did he take the average of the seasons, as they are with him, as a basis? In that case, as the seasons with him average better than with bee-keepers generally, to them the cost would be even greater than to him. Then I should like to know how much of the cost is labor, and how much capital. May be he is extravagant with labor. Not long since, if I remember correctly, he gave it as a reason why he preferred a hive whose frames required handling to one which could be handled in two sections to accomplish the same purpose, that he enjoyed handling the frames—that he got his pay in fun. It may be that Mr. D. and some other bee-keepers may grow fat on fun; but I am pretty sure that our wives and children will not grow fat on the fun that we alone enjoy. We may well inquire, too, whether he figures in this kind of labor to make up the 13 cents cost, and so is contriving to get full pay from each of two sources. At all events, it requires no argument to show that it would not do to permit the cost of honey to reach 13 cents per lb. If it were a necessity to permit it, but few of us would remain in the business.

There is no one but will admit that we should keep the cost down to the lowest possible point, and all would be glad to know what that point is. Of course, there must be no extravagance in buildings nor in supplies, and there must be no loss of valuable time. I have made, and submit tentatively some estimates which may, at least, serve as a stimulus to further calculations, as well as a conclusion to the suggestions I am making. For my figures I have taken 150 colonies as perhaps the average number that could be kept profitably in one place. The expense is made up of what may be called the fixed charges; i. e., those that are the same, whether the crop is large or small, and the variable charges, which are made up of those expenses which vary with the amount of the crop. The larger the crop, the less, of course, is the cost per pound; and my figures are made so as to bring this out somewhat in detail. I estimate the value of the necessary plant as follows:

Shop and cellar	$300
Tools, cases, and extras	150
150 colonies of bees at $5.00	750
Total	$1200

So my table will stand thus:

FIXED CHARGES.

Interest and wear and tear on plant, at 10 per cent on $1200	$120
One man 6 weeks during honey-harvest	45
Taking bees into and out of cellar	5
Other manipulations	5
Total	$175

VARIABLE CHARGES.

Cost per each 1500 lbs. surplus, being an average of 10 lbs. per colony.

2000 sections	$ 7.00
Foundation	10.00
Fastening in foundation	1.00
Putting sections together	1.00
Crates	10.00
Packing	4.00
Commission and freight	17.00
Total	$50.00

Total cost of a crop of 10 lbs. on the average, or 1500 lbs., $225.

To this must be added $50 for each additional average of 10 lbs., whence we get the following results:

With an average of 10 lbs., the cost per lb. is 225 divided by 1500, which gives .15.

With an average of 20 lbs., the cost per lb. is 275 divided by 3000, which gives .0916.

With an average of 30 lbs., the cost per lb. is 325 divided by 4500, or .072.

With an average of 40 lbs., the cost per lb. is 375 divided by 6000, or .0625.

With an average of 50 lbs., the cost per lb. is 425 divided by 7500, or .056.

With an average of 60 lbs., the cost per lb. is 475 divided by 9000, or .052.

With an average of 70 lbs., the cost per lb. is 525 divided by 10,500, or .05.

Calling the market price 15 cents, and taking a further step, we have the net profit in each case as follows:

Crop, lbs.	Price.	Value.	Cost.	Net profit.
1500	15 cts.	$ 225	$225	$ -
3000	"	450	275	175
4500	"	675	325	350
6000	"	900	375	525
7500	"	1125	425	700
9000	"	1350	475	875
10500	"	1575	525	1050

These figures are far from discouraging, but they speak powerfully for keeping expenses down. In an average location, one who spends 365 days in the year on 150 colonies can not expect to get rich; but by making six or seven weeks do, he can make his investment pay well. the difference in the number of colonies in different apiaries, the presence of buildings or cellars that can be used without expense of making special buildings and cellars, and the difference in average yields in different localities makes a great difference in the net cost of honey; yet though our circumstances vary greatly in many ways, we can, nevertheless, by severally calculating the cost in our respective cases, assist one another in putting the business on a more stable basis than it has hitherto occupied.

R. L. TAYLOR.

The president was so modest that he passed right on to the next topic on the program before the bee-keepers present could enter into any discussion. But during all the sessions the subject of the address would crop out. J. H. Larrabee, of the Michigan Agricultural College, thought he could perform all necessary work in a well regulated apiary—in fact, do every thing in connection with the business, from the folding of sections to putting in starters, to the final disposition of the honey crop on the market, and yet allow only half a day's time for each colony. That is, 150 colonies would require 75 days; 300 colonies, 150 days. It was suggested that the average bee-keeper could not afford to do *all* the work—that it would be cheaper for him to hire cheap labor to perform such work as folding sections, putting in starters, providing crates for the hives, scraping the sections, etc.; that the time for each colony might be thereby reduced very materially, leaving the expert or owner of the bees to do expert labor, such as getting the bees into proper condition for a honey crop, managing the swarming, putting on and taking off the sections. Some argued that Mr. Larrabee was too economical of time, and wanted to know what would be done about swarms. Some one suggested caging queens until the swarming season was over; others dividing, and still others using drone-traps or automatic swarmers. It was too expensive to keep a man in each yard to look after swarms.

The question finally turned to the importance of handling hives instead of frames. I was called upon to tell what I knew about it. As I have already made myself sufficiently plain in previous numbers, I will not go over the ground here again. Mr. Taylor then explained how he could find queens in the Heddon hive with the shake-out function, and how he could ascertain the amount of brood by simply dividing two sections of the brood-nest.

Taking every thing into consideration, it was plain that bee-keepers had become accustomed to putting too much time upon their bees; that the only way to reduce the cost of honey per pound was by handling hives instead of frames, or, as some of us preferred to put it, diagnosing hives more and handling frames less. As to the cost of comb honey per pound, Secretary Hilton said that, prior to four or five years ago, his crop averaged him, from one year to another, about 4 cts.; but during the last three or four years it had gone up pretty high. In one yard which he had on shares, if I remember correctly, he said the average cost of comb honey per pound was $1.00. He had had enough of that.

There is one very encouraging feature in President Taylor's address; and that is, that a bee-keeper may make a slight margin of profit, even when his average is only 20 lbs. per colony. This is a fruitful theme, and Mr. Hilton has promised to give us some more positive data on the subject in a future issue.

BEST ALL-PURPOSE BROOD-FRAME.

Mr. Larrabee, in a well-written paper, discussed this subject. It was not difficult for each one, he said, to decide upon one for himself; but no *convention* of bee-keepers could agree. The essential feature of an all-purpose brood-frame was, that it should have a top-bar thick enough so as not to sag, and from $1\frac{1}{16}$ to $1\frac{1}{8}$ in width. He liked the narrow bottom-bar that Bro. Root had recently introduced, for the reason that bees build combs down to it better; and with such a frame, when withdrawn from the hive, there was less danger of rolling over or killing bees. The queen also was less likely to find a hiding-place between the bottom edge of the comb and the bottom-bar. Frame-ends should be at least $\frac{3}{8}$ inch thick. As to whether they as a whole should be of the fixed or self-spacing style was a point upon which he had not yet decided. He urged that all bee-keepers, as soon as practicable, adopt a standard size; and that standard size, in the United States at least, was the Langstroth. Mr. Larrabee then read replies from a number of prominent supply-dealers, all of which, with one exception, indicated that thick top-bars are about to displace all frames with the narrow and thin top-bar.

I was called upon to give my experience with the thick top-bar. Most of our readers know what I think about them, so I will not take space to repeat it here. But I was surprised to see how many there were who testified to the value of the non-burr-comb frame, after an experience of from one to three years. I was interested to note, also, how many, both in convention and in between sessions, signified their intention of adopting Hoffman end-bars, or some style of fixed frame.

EPILOBIUM, OR WILLOW-HERB.

I was indeed surprised to hear so many testify to the value of epilobium as a honey-plant. In some places it is called willow-herb, and in others, I believe, fireweed. In localities where it grew profusely, even during the last poor seasons, it has yielded well. At the hotel table it was my pleasure to sample some of that Mr. Hilton had brought in, on buckwheat cakes. In body and color it was all that could be desired, and in flavor superb. If I had taken it at the first course, my opinion as to its qualities might be taken at some discount; but I tasted it after having eaten a hearty dinner; and ordinarily the keen relish of taste must have been dulled some.

TRYING NEW THINGS.

W. Z. Hutchinson, of the *Bee-keepers' Review*, read a very interesting paper on the subject above. Bee-keepers, he said, are given to trying new things. They are ready and eager to invest their hard-earned dollars in new-fangled traps. It is unwise to invest in and accept every thing that is new, as good; and it is equally unwise to reject every thing simply because it is new. We are to choose wisely. To an experienced bee-keeper a description of an article, device, or method, is all he may possibly need to decide regarding its practicability; but many are given to jumping at conclusions without carefully weighing and testing. Among the new things, he mentioned the later varieties of bees, automatic swarming-devices, bee-escapes, etc.

At the conclusion of his paper a lively discussion took place in regard to the Punic, five-banded, and Carniolan bees. The two latter had their advocates, as well as those who had found them wanting; but the Punics no one seemed to know very much about.

AUTOMATIC SWARMING-DEVICES

was another new fad that was discussed. A few had faith in them, and thought they would some time amount to something; but the chief objection seemed to be their expense, and failure to get all or a large part of the bees of the swarm into the new hive. It was argued by President Taylor and others that the labor of attaching them to the hive, and helping them to complete the unfinished work, would be very nearly as much as hiving the swarms outright. Mr. Hutchinson had faith in them.

THE BEE-ESCAPE.

There was no dissenting voice, so far as I can remember, as to the great value of this labor-saving device. A number testified how much time it had saved them, and what fun it was to take off crops of honey. Mr. Larrabee said his brother had taken off 2700 lbs. of extracted honey without so much as brushing or shaking the combs, the bees being freed from the supers by the bee-escape. Some one asked Mr. Larrabee what sort of escape his brother used. It was one of his own construction, on the horizontal-cone plan. As many of our readers may be interested in this escape, we hereby ask one of the Larrabees to send us one of the escapes, with description, and we shall be pleased to place it before our readers.

Mr. Ray and President Taylor had used with satisfaction Dr. Miller's bee-tent, the same thing that was described in GLEANINGS several years ago. They piled up the supers, put one of these bee-tents on the top case, and let the bees crawl out at their will. I believe they said they hastened the matter by shaking out as many bees as possible in the first place, and then smoking them upward.

Among other new things were the late methods of wiring. M. H. Hunt preferred the old style, with perpendicular wires, and secured perfect combs. One or two others had tried the Keeney plan with good results; but I, of course, argued for the horizontal wiring, as being cheaper and requiring less labor.

WINTERING IN MICHIGAN.

A. J. Acker, Martiney, Mich., gave us an interesting talk on the subject of cellar versus outdoor wintering. He did not have success with the outdoor plan, and finally necessity obliged him to winter indoors. His plan was, to have the covers sealed down, and set the hives on top of trays four inches deep, one end of the tray being open for an entrance. This gave ample bottom ventilation. For a winter repository he used an upground cellar, something as G. M. Doolittle has lately described. In these he puts his colonies, piling them in closely, but each hive having a four-inch space under the frames. The results had been most excellent. J. P. Berg, Traverse City, Mich., the fun-maker at this convention, not so much for *what* he said as for his *manner* of saying it, wintered both ways; but colonies that wintered outdoors in chaff hives not only wintered the best, but were stronger in the spring, and cast swarms earlier. Geo. E. Hilton, M. H. Hunt, and J. H. Larrabee corroborated this testimony, and stated that that was the general experience in their localities. President Taylor could do nothing at outdoor wintering, but indoors he had success. There were advocates at this convention of both plans; and it seemed to me, as I listened to their testimonies, that, while one wintered indoors and the other outdoors, the result was due largely to locality. I learned afterward that there was a great difference in Michigan localities. Where it was very cold, there cellar wintering generally prevails; and in milder places the outdoor plan gives better results.

BEE-KEEPING AND OTHER BUSINESS.

Mr. W. E. Gould discussed the question as to what business can be combined with bee-keeping; and Mr. A. J. Pierce, a little later on, the subject of bees, poultry, and fruit. The two topics naturally covered the same ground; and in order to save space I will endeavor to give the gist of both discussions in one. Mr. Gould argued that, where one had two or three out-apiaries, he was, in a sense, a specialist, and therefore would hardly have time to do much with any other business; but if he had only one yard of only a hundred colonies, it might be well for him to consider what other business he could combine profitably with it. Localities and men differ very much; and what would be a success with one would not necessarily be so with other men in other locations. Other things might be combined with the bee-business, such as fruit culture, teaching school, and poultry-business. Mr. Pierce, from the standpoint of the fruit-grower, gave some valuable suggestions along this line. Fruit and poultry combine very nicely together. The latter help very materially to diminish insects on the fruits, such as the destructive curculio on the plums. The small breeds of poultry, such as the Leghorns, are better for this purpose. The Asiatic kinds are not so good foragers. The manure from eight hens is equal in fertilizing value to that from one cow. As with bees, fruit-men sometimes experience poor seasons. At such times the poultry and bees are a great help, and make all the difference between profit and loss. It seems to be a recognized fact, said Mr. Pierce, among all fruit-men, that bees are necessary to the proper fertilization of the blossoms; and if his neighbor didn't own bees, he must have a few colonies for himself. It would pay him, even if he secured no honey. Mr. Berg gave us some excellent suggestions along this line. He is both a fruit-grower and a bee-keeper, and he found that his poultry had so reduced the evil resulting from the curculios in his plum-orchards that the curculio was not to him a pest. In fact, he *wanted* a few to kill off some of the fruit, as his trees would bear too heavily otherwise. Along with these discussions came up the matter of

SPRAYING FRUIT AND POISONING BEES.

This convention, like the North American at Albany, furnished abundant proof to the effect that bees have been poisoned in great numbers when the trees have been sprayed during the time of blossoming. Mr. Pierce gave us some of his own experience. He had had his apiary nearly cleaned out by a neighbor who had sprayed his trees during the time of bloom. This neighbor did it ignorantly, and stopped at once when he learned of the consequences. The bees had been in the most promising condition for a good honey crop; but the spraying had utterly ruined its prospects. The neighbor in question followed the directions of the pump-maker; and it was suggested that all pump-makers or manufacturers of spraying-apparatus be labored with, who advise spraying during fruit-bloom. Two or three bee-keepers, Mr. Pierce among the number, said that, so far as they had learned, they were all very glad to modify their directions as soon as they were informed of the evil results to the bees. The opinion seemed to prevail that, as soon as fruit-men and manufacturers of spraying-outfits were properly informed, bee-keepers would have no further trouble; although it was urged that every State pass a bill, more for its educational effect than for legal coercion.

A PECULIAR BEE-DISEASE OR MALADY.

There was only one lady, Mrs. Delia Coop, present at this covention, and she had come to seek light on a certain peculiar malady which she had found in her apiary. She was not sure whether or not it was foul brood. The brood in the imago state died before coming to maturity. There was no foul odor; and the peculiarity of the whole case was, that the immature bees, instead of having heads turned toward the cappings, were reversed, with their heads toward the midrib of the comb. The trouble seemed to be contagious and constitutional. The disease or malady had existed in her apiary for a couple of years, but was not present in any other yards in the same vicinity. Poison was suggested as a possible cause; that the larvæ, weakened thereby, were unable, just before entering upon the imago state, to reverse their heads for the last time, and in their unnatural condition died. But the lady explained that the bees had had no access to poison, as it was past spraying-time, or when other poisons were used. We were unable at the convention to suggest any thing else than the poison theory; but as this will appear before thousands of readers, there may be others who have seen similar cases, and have ascertained its cause. If they are able to give us any light on this point, we shall be glad to have them do so.

THE USE AND ABUSES OF FOUNDATION.

Mr. M. H. Hunt, of Bell Branch, read an essay on this subject. The intelligent use of foundation, he said, had added to the profit and pleasure of bee-keeping. Attempts had been made to make combs the full depth of cells, and all had led to failure. Even if successful, such combs would be of no practical value to the bee-keeper, their bulk being so great that freight-rates would forbid their use. He recommended full sheets of light brood foundation, wired on the perpendicular plan—the sheets to be cut to the exact full inside measurement of the frames. By the use of starters in brood-frames, perhaps bees will enter sections sooner, but that is not the only thing desired. Drone comb would be apt to be the result unless great precautions were taken, such as young queens and first swarms. The abuse of foundation was the manner of putting it in. As his sheets were cut to the full size of the frame, he fastens the edges by pouring melted wax from a spoon around the edges, the point of the spoon being narrowed to make a fine stream.

The election of officers resulted as follows: President, R. L. Taylor; Vice-president, J. H. Larrabee; Treasurer, M. H. Hunt; Secretary, G. E. Hilton. The next place of meeting is Lansing.

THE VISIT OF MR. C. P. DADANT AND HON. J. M. HAMBAUGH.

THE KODAK FIEND; THE WINTER PROBLEM; POLITICS AND BEE-KEEPING.

By Ernest R. Root.

The Dadants have been perfectly free in giving us some of the kinks of the trade in foundation-making, and I have long desired to reciprocate. In response to my repeated invitations to visit Medina, Mr. Dadant finally told me, at the Albany convention, that he had decided to go home with me, taking with him his friend, the Hon. J. M. Hambaugh. This was indeed a double pleasure.

I have sufficiently introduced the representative of the largest foundation establishment in the world, so that our readers are quite well acquainted with him; but with Mr. Hambaugh there may not be the same acquaintance, and I am very glad of this opportunity of introducing him more fully.

Hon. J. M. Hambaugh is not only a prominent and successful bee-keeper of Illinois, but one of their legislators. He was elected as a member of the House of Representatives, and was one of the famous 101 Democrats who finally succeeded in electing J. M. Palmer to the U. S. Senate. Those who are familiar with the facts will remember that, in the House of Representatives of the State of Illinois, there were 101 Democrats and 100 Republicans. Besides these there were three Farmers' Alliance men. In order to elect their senator, the Republicans would have to win over to them the three Alliance men, or the Democrats two of them. After voting and adjourning day after day, with no result, the Democrats finally elected their candidate by securing two of the Alliance men. Mr. Hambaugh, besides being one of this famous 101, will be remembered as the one who introduced the bill, which passed both houses, securing to the State Bee-keepers' Association an appropriation of $500 annually. He also introduced another bill, which nearly passed, regulating the matter of spraying fruit-trees in such a way as not to be detrimental to bee-keepers. This bill would have passed, but it was near the close of the session, and was simply held over.

At the close of the last day of the Albany convention, Mr. Dadant and Mr. Hambaugh, together with your humble servant, boarded the train for Medina. And then we talked as only three bee-keepers can. We covered the whole round of bee-keeping; but as we had an "honorable gentleman" in our crowd, we drifted more or less into politics. Messrs. Dadant and Hambaugh would continually fall into argument, while the third member of the trio listened. I do not know how the other two felt after they arrived at Medina; but it is sufficient to say that my sides were sore from laughing over the good-natured sparring that passed back and forth between the two Illinois men.

We arrived at Medina on Saturday morning, and the visitors were then escorted about the Root establishment by our business manager, Mr. Calvert, while your humble servant looked after the matters that had been left until his return. In the afternoon, as they were obliged to take the evening train I went with them through some of the other departments. We tarried some little time in our foundation-room. I noticed Mr. D. watching one of the girls roll off foundation. A smile began to play over his face.

"What now?" said I.

"I guess," said he, "there is one of the kinks that you people haven't learned yet."

Mr. Dadant observed that the foundation had a fashion of sticking to both rolls as it came out, tearing the wax, and making it difficult to secure the end free from both rolls. He stepped forward and dipped his hand into some cold water, and allowed the water to drip on the upper roll, and, presto! as if by magic the foundation stuck the next time to the upper roll, and pulled off easily. This was something that we hadn't yet got hold of, and we are glad to give it to the bee-public for what it is worth. Mr. Dadant explained that the reason the foundation stuck to both rolls was because they were of the same temperature; that you could make the wax stick to the upper roll by cooling it slightly.

After looking over things inside of the buildings, we rambled over to the "yellow house," as we call it, where we keep all sorts of implements that are sent in for our approval or crit-

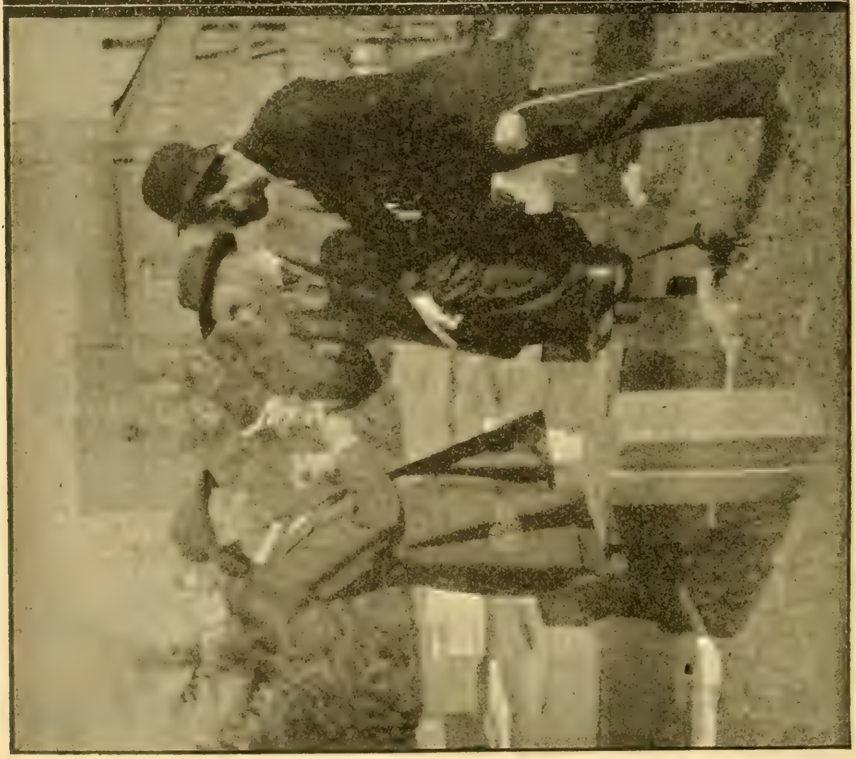


FIG. 1.—SOLVING THE WINTERING PROBLEM.

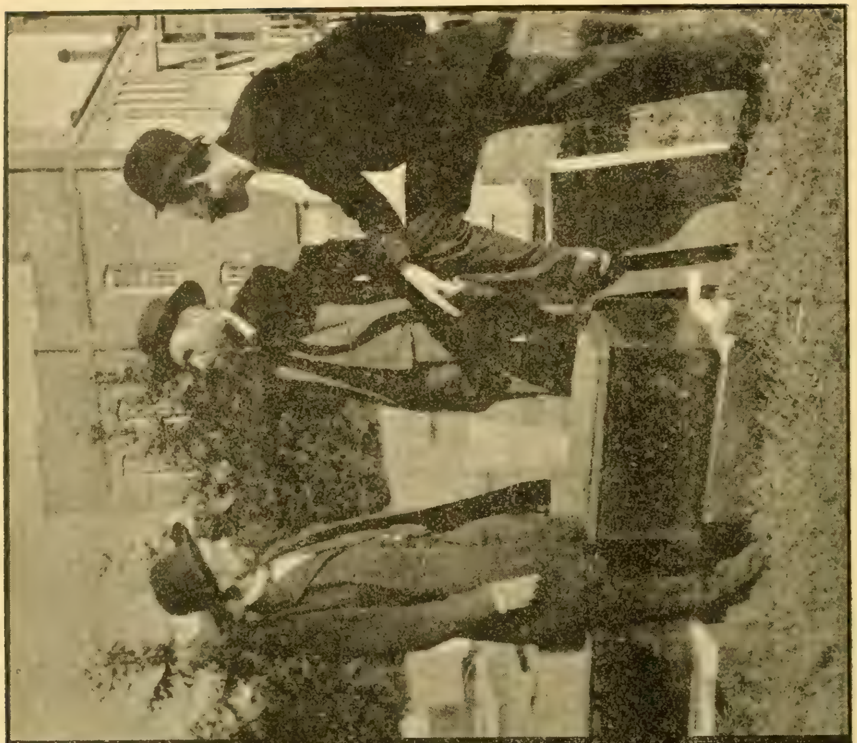

FIG. 2.—WINTER PROBLEM SOLVED.

icism. Among other things, I showed the gentlemen the Hetherington Quinby hive, and how it differed from the original Quinby. While Mr. Dadant acknowledged that it was better than the original hive, and while it might be the only thing that the bee-keepers in York State, among the hills, could use, he could not tolerate it for his section of country he was sure. Mr. Hambaugh took no particular side in this discussion. We next went out into the apiary, where I showed them what experiments I was making in the matter of outdoor wintering—why I was gradually leaning toward having no absorbents over chaff-packed colonies, and why I was beginning to believe that a sealed cover, covered with plenty of packing material, was better. Mr. Dadant disagreed again. Of all the experiments they had made, they had come to the decision that absorbents are quite necessary for outdoor wintering. I showed them outdoor colonies packed both ways; but it was too early in the season to notice any practical difference. We finally strolled over to that portion of the yard where the Shane bees are located, and which was illustrated recently. The hives of this apiary are all inside of our new outside winter packing-cases. Mr. Hambaugh and Mr. Dadant both seemed to like the arrangement.

But I must not forget to tell you a little incident that happened while we were in the yard. The two Illinois men were discussing the methods of wintering outdoors. As they disagreed on politics, so they disagreed here. Of course, I did all I could to make the discussion wax warm; but to me they paid no attention, so intent was each in making his point. Very fortunately for our readers, a Kodak fiend happened to be near the scene, and secured a picture while they were in the height of discussion. Fig. 1 is the result—a snap shot, as you see.

A few minutes later, they came to an understanding; and after all their talk they found they agreed after all. At this juncture this same Kodak fiend took another picture. Well, he and the writer were working in collusion, and I have secured the pictures.

Those who are acquainted with the gentlemen will at once recognize them; and Fig. 2 shows the disputants just as they had come to an agreement, and had said, "Oh! I see now what you mean." But even then they would not listen to me, although I had been talking to them about the winter case. They finally turned to me, and I presume they noticed a smile of triumphant pleasure on my face, for I had just seen the Kodak fiend slip out of sight with his treasures of pictures. "Root is cooking up some mischief," said Dadant; but I protested my innocence. When I bade them good-by as they took leave on the train, they both seemed to think that I had gotten them into some sort of "trap." Their last words were, as they sung out, "We'll get even with you."

◆

FIXED DISTANCES.

WHAT AN AUSTRALIAN THINKS OF THEM.

I am somewhat puzzled at some of your bee-men advocating eight frames in the brood-nest. I am using ten, Langstroth size, and these are not sufficient for the queen, and she takes charge of three of four frames in the upper chamber. With regard to frames at fixed distances, about six years ago I gave you a description, with drawings, of the hive and frames I devised and had in use. You pronounced it a good hive, but said bee-keepers in America could not tolerate frames at fixed distances. However, I have stuck to it, and have taken first honors every time at the exhibitions; and now I find the Americans are coming around to my way of thinking, and I don't think they will regret it.
THOMAS DIXON.

Masterton, New Zealand, Nov. 28.

[Difference in location makes considerable difference as to the size of hive. The 8-frame hive gives the best results for most localities.]

LADIES' CONVERSAZIONE.

SPRAYING FRUIT-TREES AN INJURY TO BEES.

OUT-APIARIES IN POOR SEASONS.

Have any of the friends in bee culture experienced trouble from bees dying off because fruit-trees were sprayed near their apiary? Mr. Axtell sprayed our fruit-trees and vines four different times, but sprayed none while in blossom, but at the right time after the fruit had set, as per A. J. Cook and Wm. Stahl, of Quincy, Ill. Our bees, when taken from the cellar, were in fair condition, and seemed to prosper as well as bees usually do in the spring, all the while having all the brood they could take care of, so that the most of our colonies, we thought, would be strong enough to gather honey when white clover came, without further building up. This time of looking through them was about the time apple-trees were sprayed. Two weeks later, in looking through they were no stronger, and we feared that not many would be strong enough for the honey harvest, so we took out brood from some and built up others, so as to have as many strong as possible, and yet they did not build up. There seemed to be but few old bees in the hives the first of June, although the combs all the while were full of brood, and covered with young bees; but they seemed to die off as soon as they began to work. This was the condition of the hives all through June in our home apiary.

At our out-apiary, four miles away, near the timber, the colonies were not thus affected. They were wintered out of doors, and built up into fine strong colonies by the first of June, nearly every colony, and gathered some 500 lbs. of surplus from honey-dew besides increasing to as strong colonies as I ever saw; yet there was no swarming. They seemed to know what a long dearth of honey was before them.

In the home apiary there were so few old bees that they could not even fill up their brood-combs with honey. There was a strip of hickory timber about one mile away, from which they gathered some honey-dew—enough to have caused the colonies to become populous. They were not so strong on the first of July as they often are no the first of June. Could this have been a case of common spring dwindling? It seemed different from any thing we ever had before, as, in other years when we had spring dwindling, they died off as soon as taken from the cellar, which they did not do this spring. They acted just as if some one had poisoned them; but we have no reason to think any neighbor or any one else would do so. If poisoned they must have got it from the vines and trees at home, perhaps sipping water from the leaves or from the forks of the branches or limbs of the trees weeks after. Mr. Axtell thinks it was not from spraying the trees, as he watched the bees for several days after, and could never see bees sipping water from the leaves. But I have feared that it was. What do others think? Have they heard of such a case before? I think I shall feel sorry to have our trees sprayed again, for our honey crop is worth much more than our fruit crop, when we have clover honey; besides, our apples are just as wormy as those of our neighbors who did not spray their trees. The apple-trees were sprayed three times—twice with London purple and once with Bordeaux mixture. They fell off badly through the fall also. If it were poisoning from spraying, I should not have thought it would have lasted so long. I could not see any more dead bees in front of the hives or in the apiary than usual. I could see no dead bees or dying bees, that acted as if they had the nameless bee-disease. The rest of the season they did as well as bees could that gathered scarcely any honey. The last of June we took 40 colonies to another location near a timber three miles away, and 20 to another location in an opposite direction, hoping, by leaving but about 70 at home, they would all build up without feeding all summer, as they were getting a living at home, and storing honey at our out-apiary where there were over 100 colonies. We visited each little out-apiary, and saw they were improving, and thought they would take care of themselves, as there were so few of them; but we fed the home apiary some the middle of August.

This fall, when we visited them, expecting to find they had enough for winter, we found very weak colonies, so that we brought them all home again and doubled them up, putting two and three together to winter them, and fed all or nearly all their winter stores. Now, if we had left them at home, and fed them in August a few dollars' worth of sugar syrup, to the amount of the expense of moving them, they would have been much better off, so that we have concluded it pays better in poor years to keep our bees at home and feed some. During good years this location can as easily support 125 or 150 colonies as 50. If they are away from home we are apt to neglect them much more than at home. It is an easy matter to run out to the feeder with a few pails of sugar syrup, and give them a feed now and then; but when we have to feed at an out-apiary it is much more laborious.

At the timber apiary, in the spring we had several hundred brood-combs not in use. We gave them to colonies to put the honey-dew in, rather than have so much stored in sections. The colonies built up very strong—nearly as strong, it seemed to me, as colonies do at swarming time, but none swarmed. They must have had from 40 to 90 lbs. in the brood-nest, so that we felt quite sure of having strong colonies this fall to gather the fall harvest, and so we did; but they had used up nearly all their honey; and as there was no honey coming in to cause the queen to keep up laying, when we came to feed this fall we found the colonies were only about as large as those at home. Some colonies which I saw had two or three combs of eggs. The eggs were all removed—because no honey was coming in, I suppose. So I think it is only guesswork as to which is the better plan—to have strong colonies at the close of the spring honey harvest, that eat much honey through the summer, and are strong in time to gather the fall harvest, which fails us about half the time, or to have small colonies during summer that do not require so much honey to live upon, and are small, consequently, when the September harvest comes in. We fed, both home and out-apiary, granulated-sugar syrup in the spring—nearly all they had to live on, so that it was not poor feed that caused one apiary to dwindle and the other to prosper.

Roseville, Ill., Nov. 10. Mrs. L. C. Axtell.

[We can hardly believe that, if you followed spraying as directed by Prof. Cook, the bees at your home yard suffered from it. Some other cause is more likely responsible for it. So far the testimony has always been that no bad results followed the spraying if administered *after* the falling of the blossoms. Perhaps some of our extensive bee and fruit men of Michigan or elsewhere can give us some light on this matter. We presume that, ere this, you have seen the testimony in the Albany convention report, and in the Michigan, in this issue, to the effect that spraying *during* fruit-bloom is decidedly destructive to bees.]

NOTES OF TRAVEL

FROM A. I. ROOT.

Dec. 12.—Oh, yes! about that pretty moss that coats and covers the rocks. Well, that is not all it does, for, on going about the city, I find that it even covers the roofs of the houses, and it does make them look funny enough. Every roof of any age at all, with its "moss back," makes one think of the "old oaken bucket" of childhood's memory—"the moss-covered bucket," in very truth. My friends tell me this heavy coat of moss does not rot the shingles very much; but as I see our next-door neighbors taking the pains to scrape it off, I confess to being a little skeptical. These magnificent forests, the thrifty-looking fruit-orchards, the beautiful waterfalls, and last, but not least, the moss on the roofs, is the result of the frequent and copious showers, both winter and summer, and, in fact, the year round. Add to this, rivers and bays, so that steamboats go almost everywhere, and do you wonder that there has been a great stampede for Oregon and Washington?

Dec. 24. I suppose I might as well own up that I have been sick. I thought for quite a spell I would say nothing about it; for you have heard almost enough about doctors and medicine already; but as there seems to be quite a lesson right here, I think I will give it to you.

Well, you know I advised calling a doctor, when you need one, from among your own neighbors—a good man from among your acquaintances. But suppose you are a stranger in a strange land, what then? Why, inquire about and find a doctor in good practice that is generally well recommended. That is just what I did in Portland, Oregon. I had been suffering from a severe cold for almost two weeks, and it had settled into a fever, so I thought it must be "lung fever." The doctor, however, said very decidedly that it wasn't lung fever. After a little examination he said, "Your lungs are quite sound. Your cough and cold is a bronchial trouble."

I could hardly believe this; but as it is the third time I have been told much the same thing by as many prominent physicians, I was obliged to believe it. Then he said almost exactly what our doctors away back in Ohio had said—"My dear sir, the real seat of your trouble is a broken-down nervous system; and if you have at present any business on your hands, just get out of it as soon as you can."

I told him I was on a pleasure-trip solely for my health; and he resumed:

"The immediate trouble just now is, however, that you are bilious. Before the quinine you have been taking for your cold can do any good you must get your stomach in trim. What have you been eating lately?"

"Why, doctor, that is the great trouble. I can't eat any thing—nothing tastes natural, unless it is oranges, grapes, lemonade, or something of that sort."

"Oh! but these are the very things you must *not* eat. I'll get you out of this snarl; and now, mind you, you are to have only milk, meat broth, pure water 'straight,' no lemons or sugar, nor any thing of that sort."

"But, doctor, how about the 'cravings of nature being an infallible guide,' etc.?"

"The cravings of nature may be all right, and, again, they may be all *wrong*. Reason and experience must guide and direct even nature's calls."

He prescribed for me, and thought I would be ready to go on in a day or so; but one day, before I had got free from the fever, a friend drove up with a buggy, and wraps enough to give even a sick person an airing safely, and I consented to go over to Mt. Tabor to see a field of Everbearing strawberries. The day was pleasant and warm, and I thought the air would do me good. Dear reader, don't ever try to take a buggy-ride while you have a fever. It doesn't work well. In two or three days we called the doctor again, for I was having chills and fever every day. He pronounced it nervous malarial fever, the same as I had last August.

"Now look here, doctor, has this fever got to have a run of three or more weeks? and had I not better send at once to Ohio for my wife?"

"Oh, dear! no—at least not just yet. I'll fix that fever, at least I think I will."

"But, doctor, this cough I have every night will kill me if it isn't stopped."

He left a prescription for the fever and another for the cough, and said he didn't think I would need to have him called again; but if I did *not* get right along, to send him word.

Now, I was inclined to get exasperated. He wasn't in the house more than twenty minutes, and yet seemed so sure. He said my lungs were all right, that I wouldn't have another run of the fever, and that he could stop the cough. He charged $2.50 for each visit, and I was very much inclined to lose faith in him, and doctors and humanity in general. But everybody said that *Dr. Geisee* was all right, and so I submitted. The fever next day was later and milder; and the day after still more so; and the cough began to abate, so I became more reconciled to my milk-and-water diet, and in a week I was ready to travel again; but I felt very much as I did after my fever of last fall. The moral of this is, that, without a physician's advice, I should have done just the wrong things. Another moral is, that there is progress in medicine as well as in other things. If the intelligent, educated young doctor of the present can tell you in twenty minutes just what you need to do to get well, it is cheaper to pay $2.50 for it than to have a doctor call in every day for a week, even if you pay him only $1.00 for each visit. I am pleased, also, to note the perfect agreement between the skilled physicians of Ohio and one from so far off as Portland, Oregon.

Now, dear reader, I am ready to go on with my story.

Portland, Oregon, is a progressive city of about 60,000 people. They don't have any cellars under their houses, because stuff so seldom freezes in their ordinary rooms, and because so much rain would fill their cellars. Neither do they have cisterns. The water out of the river, sent all over the town by the waterworks, is so very soft they don't bother to make cisterns. They don't have any alley or back streets. Every street is a front street. The consequence is, all rubbish is pitched out in front. As every one burns wood, and as the wood is all pine or cedar, which is quite bulky, the wood business is quite an industry. The wood, in four-foot lengths, is dumped in front of each dwelling. Then the wood-sawing machine comes along. It is a two-horse engine aad boiler, mounted on something like a dray, drawn by one large horse. A large buzz-saw stands at the rear end of the dray, and two men will saw up a cord of four-foot wood in ten or fifteen minutes. As they get 50 cts. per cord, fuel to run the engine thrown in, they do very well. The wood is then got into the woodhouse and split as needed. As it "always rains" in Portland, it is one of the fine arts to get the wood dry.

I have never seen in any city such beautiful lawns, and so many of them, as I saw in Portland. The abundant rains, and no frost to make the lawns ever look brown, explains it. I saw hardy roses in full bloom in the open air, in the middle of December. People were making garden and planting peas at the same date. The peas come up and grow more or less all winter; and when spring comes, they push up and make pods very quickly. Cabbage-plants are also set out in the fall, and any time during the winter when most convenient.

I had a very pleasant visit from Mr. D. Kauffman, of Needy, Oregon. He told me of having his bees gather honey from the willow in February, during one season, so they stored in the sections as high as 30 lbs. per colony. The principal honey-plant among the mountains is an evergreen shrub called "fal-lal." Friend Kauffman very kindly presented me, and the friends with whom I was staying, a nice lot of beautiful honey from that source.

There are a good many Chinese in Portland, and many of them, I am told, are men of wealth. For the first time in my life I saw here a Chinese woman on the streets. She was richly dressed, much as the men dress, only she wore nothing on the head. I am told they are always bareheaded when on the streets, no matter what the weather is. Judging from a single specimen, I should call Chinese women very graceful and pretty.

As I moved out of Portland (Dec. 21) on the way to Seattle, Washington, I was much stirred by the sight of the steamboats on the river. It reminded me vividly of a similar sight when I was attending school, almost 40 years ago, on the banks of the Ohio River. Oh what beautiful green fields, right here in winter time! Yes, and gardens too, and orchards, where the apples are not yet picked.

Very likely almost everybody knows that there are ferryboats large enough to carry a whole train of cars; but I shall have to confess I had no thought of such a thing until our train actually ran on such a ferry to cross the Columbia River. There were three tracks on the ferryboat, and the train was divided into three sections. The boat was so large that the weight of the locomotive and train hardly sank it perceptibly. As we left the ferry I saw men pulling sturgeons out of a fishing-boat, many of the fish being as large as the men who raised them with pulley and tackle.

The Columbia River salmon is a most delicious fish, as I happen to know, for the doctor told me, when I needed some solid food besides my milk-and-broth diet, to eat fresh fish. Seattle is another new and pretty city of about 50,000 inhabitants.

A great deal of fault is found with railroad companies, express and telegraph companies, etc. I want to say a word of praise for the latter. On Monday, Dec. 21, my good wife felt as if she could stand it no longer to think I was sick with my old fever, and she not near me, so Ernest sent me the following telegram: "Mother wants to go, if you are willing. Wire answer."

I do not know what time Monday this was sent, but it went to Portland; and, finding I had gone on, it traced me to Seattle, found the hotel where my name was registered, and at twenty minutes before midnight the clerk wakened me and handed it in my door. Before the clock had got to 12 I wired back, "I am quite well now. Better await letter from me."

Well, even at that hour of the night the telegraph company sent a messenger to receive and send off my answer, without charge. That is, they made no charge for sending a boy at that time of night to get the telegram. The hotel clerk simply pressed a button, and this notified the office to send a boy to get an important message. For $2.00, or about that sum, my family in Ohio called to me in Seattle, Washington, to know "how I was." The hotel clerk woke me up, and I called back to them, nearly 3000 miles, "I am quite well now." Isn't it worth something to live in a country where such a thing is possible? And is it not true that we have a good many people who accept responsibility, and discharge these duties faithfully and well? I am proud of our people, and I feel it a pleasure to pay them for their faithful service.

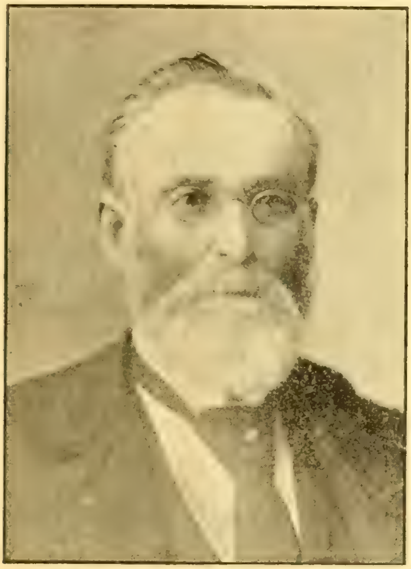
Probably most of our readers have heard of H. A. March, of Fidalgo, on Puget Sound, Washington. Years ago friend March gave us some valuable facts on how far bees fly, and these facts are embodied in our A B C book. Later friend M. has become famous as almost the only man in America who grows successfully, on our shores, cauliflower seed. Right near my elbow, while I write, stands a bag of this seed, worth about $1000; and there is more than double this amount in cabbage and cauliflower seed in the house; but I haven't got quite ready yet to tell you about friend March's gardening. While in Salt Lake City I received a letter from friend M., saying he should feel greatly honored if the President of the U. S. should conclude to pay him a visit, and that he would do his level best to make the visit a pleasant one; but that, could he have his *choice*, he *rather thought* he would prefer a visit from *A. I. Root.* Well, this explains why you find me away up here at Seattle, waiting for the steamer "Wasco" to take me to Fidalgo. I was so weak after my sickness that I felt faint when I stepped on board; but something seemed to tell me I was going to find health and strength there. As we pushed out into the waves, which were already running high, I stationed myself near the bow, where I could readily imagine the steamer was a fast horse and I the rider. Reader, if you ever get seasick, try my plan. Look straight ahead, in the direction the steamer is going; brace yourself; lean a little forward, and hold on. I soon began to enjoy it. Sea-gulls were all about us, even flying so close you could look into their eyes. And ducks and geese—oh my! how thick they are up here! There are so many varieties of both, I feared I should never learn them; and then there is a most handsome water-fowl they call "brant." It is about half way between a duck and a goose. Hunting water-fowls is a trade here; and when the day is suitable, the cracking of the guns is heard almost incessantly. Puget Sound is almost alive with ducks and geese, and very often the air is full of them. Sometimes their cackling and singing makes a constant, steady noise. When we got out into the open salt water the steamer rolled and tumbled a good deal; but I rather enjoyed it. We passed one steamboat that had got into a trough in the waves, and she couldn't get out. First her wheel would be clear up in the air, then way down under water. She tried to go back, then ahead, and we left her floundering, with the crew looking out with troubled faces. Soon we made a landing, and then, to get under the shelter of an island, *our* boat started across in the trough of the waves. Oh! but *didn't* she roll and pitch! The waves went right over her, and did the neatest job of washing and scrubbing off the decks you ever saw. Yes, the waters even washed the window where I was looking out, until I couldn't see ahead. It really seemed as if the great steamer had taken a sudden notion to dive, head first, clear down to the bottom of the sound; but just before she got clear under water she would strike something so solid I really thought at first she was bumping her head against the bottom. When I suggested as much, don't you believe my fellow-passengers were rude enough to have a big laugh at my simplicity! "Bumped against the *bottom!*" and then they "haw-hawed" again. Well, it seemed just like a big load in a buggy that makes the springs strike together every now and then. Finally some one said it was the front part of the boat striking the surface of the water, as she came down upon it. The wind increased, and so did my enjoyment, until toward night, when it was so high they tried again and again to tie up at a landing. Somebody said they would have to give it up and go by; but one of the crew said we had *got to land*, for they were out of both wood and water. Well, they finally got her tied up; but when she was loaded, the captain said it was not prudent to start out in such a gale and such utter darkness. Then I discovered that I had eaten three pretty good meals; and after the clerk had stowed me away in a nice warm berth, I forgot about being sick, and went right to sleep.

About 3 o'clock the whistle blew and we pulled loose again. I looked out; and as the moon was shining I dressed and came out to see the rest of the fun. We soon landed at Anacortes, a town of over two thousand inhabitants, where, only *20 months ago*, was an entire wilderness. This is a fair example of the way they get up booms up here in this northwestern country. About a dozen steamers touch at Anacortes every day. They have already two railroads and an electric-motor railway, eleven miles in length. Of course, there has been a wild excitement in selling land and lots for the past year.

I landed at the wharf, went to a hotel, and, as it was at least two hours until daylight, the landlord built a fire for me in the ladies' parlor, and at the proper time gave me a nice breakfast, and charged only 25 cts. for all. So you see these new towns that start up so suddenly do not always charge exorbitant prices. At Seattle I paid 75 cts. for breakfast, and no better, to my notion, than the 25-cent one.

I must not forget to mention that, away up here near the north pole, the days are very short. It gets night about 4 o'clock, and it isn't morning much before 8. Business men, many of them, open their stores at about 9 in the morning. The sun pops up a little, away off in the south, during the middle of the day, and then pops down again. But in the summer time, oh what a difference! Dawn then commences a little after 3 in the morning, and friend March says he can read a paper out in his dooryard until almost 10 at night.

From Anacortes I went 3 miles by rail to Fidalgo, and then I had a mile through beautiful woods of pine and fir to the March ranch I have read about and seen for years, only in imagination. Salt water is everywhere, for this whole country is islands, peninsulas, bays, and sounds. The forest-trees are immense, and the perfume of the firs and other evergreens is wonderfully delicious, especially to one who has been sick. I always love to see running water, and here I found enough of it, as it has been raining so much. The shrubbery and undergrowth are so thick in these woods one can hardly get through unless he follows the wagon-roads. I passed over the summit of Fidalgo Island, and came down on the eastern side. Very soon friend March's garden was before me. While in the woods, however, I was attracted by numbers of poultry-houses that reminded me of Stoddard's "egg-farm." They were right out in the edge of the pine woods, each house neatly whitewashed and just like its neighbor, may be 20 rods away. The hens, mostly Leghorns, were bright looking and healthy, and the cackling going on told of eggs, even if it was the last of December. The floors were all raised a couple of feet from the ground, doubtless to avoid dampness, and padlocks on the doors indicated that things were not managed in a loose way. As I neared the fence that divided the wood land from the garden, I noticed the rain-water running in a series of silt-basins, and from these a series of underdrains led down through his gardens to the beach. Oh what celery greeted my eyes! There are at least 25 or 30 different outbuildings around his home. I passed through the garden, through the apiary, and under a broad low shed at the back of the house. Here I stopped and looked about. An elderly man approached, and I told him I was A. I. Root. You ought to have seen us laugh and talk. Here is friend March, just as I saw him.



H. A. MARCH, FIDALGO, SKAGIT CO., WASH., THE VETERAN BEE KEEPER, CAULIFLOWER-SEED GROWER, GARDENER, AND PROPRIETOR OF PUGET SOUND EGG-FARM.

In less time than I can tell it the whole ranch was at my disposal. I began to take in great breaths of strength and enthusiasm all at the same time. In the first place, for the first time in my life I saw before me a *successful* egg-farm. Friend M. has raised eggs as a business for more than twenty years past. He runs incubators, and hatches over 2000 chicks each year. His 800 laying hens are in about twenty different houses. While all have unlimited range, they all go where they belong, to roost. They are always fed in their houses, and the eggs are laid, also, in nests made in the buildings. They are now getting daily from 150 to 200 eggs; and at 37½ cts. per dozen they more than pay all expenses. I went over, one by one, the different obstacles usually met in keeping poultry by the thousand. Friend M. and his boys have met each drawback, and fought through it. Rats, disease, vermin, wild animals in the woods, etc., are held in check only by "eternal vigilance." It is the same way with his wonderful achievements in market-gardening. Go over his place and talk with him, and you can well understand why he succeeds when everybody else fails.

Let me give you an incident characteristic of the man: When he took a notion, about ten years ago, to raise cauliflower seed he soon found he must have water for irrigation. Back in the woods, on the hillside, he found a weak spring of water. This spring was near a line fence between himself and neighbor. As his means were then limited he made troughs of boards, nailed together and supported sawhorse fashion, to carry the water clear down to his garden. He succeeded, and began to make some money with his seeds. As more water was needed he began opening up the spring until it came clear up to the line fence. At this point his neighbor began looking on and finally demanded $25.00 a year for the water that came out under the fence. Friend March refused to pay it, and the neighbor shut the water off, to bring him to terms. Friend M. "looked the ground over," and found a wet-looking place on his side of the fence, a little further up, so he and his men turned their ditch alongside of the fence up toward this wet spot. They kept going into the hill, until at the upper end they were *14 feet* below the surface. While the work was going on he happened to be going up with his son, and they noticed a great volume of water pouring down the troughs. Supposing the men had probably let it off where they had dammed it up he remarked:

"Al, I would give a thousand dollars for a spring that would give us water like that," and just at this moment the men came rushing down to say they had struck a spring as big as a man's arm. Here was all the water he wanted on his own land, and, behold, his neighbor's little spring had suddenly become dry; for all the water, so it transpired, came from this one big vein. Now he could not only raise all the cauliflower seed he wished, but he could raise cabbages, celery, strawberries, and any thing he wished, on his whole 12 acres of underdrained and enriched market-garden ground. All the underdraining here is done with red cedar, and this 14-foot trench was soon bridged over clear to the spring. A huge tank was then constructed on the upper side of his garden, where the water is warmed up by the sun before putting it on the plants. Our friend had no money to buy iron pipes, and his ground does not lie so he can run the water in trenches, so he lay awake nights, as bee-men often do, studying out his apparatus for irrigation, and this is what he did:

He bought some heavy ducking, or sail cloth, and made his own cloth hose. A whole piece is unrolled, cut from end to end in three equal strips. Each strip is rolled up and made into a hose by double seaming on a sewing-machine. Then he put this cloth hose into a tub containing boiled linseed oil and tar, one gallon of tar to five of oil. The surplus oil is now pressed out by running the hose through a common clothes-wringer, and, when dry, there is oil enough to hold the water. For connecting these cloth tubes, a short tube of heavy tin is pushed into the cloth tube, and tied with a stout piece of twine. To prevent it from slipping apart, a bead is turned near each end of the short tin tube. He has about 2000 feet of this canvas hose, and it cost him only about 2 cts. per foot. He has used some of it for five years, and it has not broken anywhere yet. This is really doing better than rubber hose that cost us about 12 cts. per foot.

To irrigate a field the cloth hose is laid to the point in the lot furthest from the tank. One of his men now takes the end of the hose in hand and thoroughly waters nine rows of plants—four rows each side of him, and the one between his feet. As he gets the ground well soaked he walks backward; and when he gets back to a coupling in the hose he pulls the bow-knot in the string, and drops one length of hose. This he repeats until the nine rows are watered the whole length of the field; then he puts his hose together and waters nine rows more, and so on. A good man will thoroughly soak an acre in a day. When dry enough the cultivator is put on, and then a lump-pulverizer—a machine of March's invention. This machine scrapes all the lumps into the middle of the row, and then mashes them up fine. Is all this too much bother? By and by I will show you a Kodak view of a dozen stalks of his irrigated celery. They are about all *I* should want to carry. I hardly dare tell you what crops friend March *has* secured by his high-pressure gardening; but I will say this: He has, under the most favorable conditions, had a *single cauliflower-plant* give him $5.00 worth of seed. Now, mind you, this has been accomplished only by years of labor with brain and muscle. He has fought insect-enemies with all the insecticides known; and after that, he and his men have gone down on their knees and dug out the worms, one by one, that were gnawing at the vitals of his seed cauliflowers. They cut them off the living stalk, and the plants healed up and bore seed. He never gives up to any foe; and in seed-raising he is so untiring in selecting the very best plants to raise seed from that it is not strange that the experiment stations of almost every State in the Union are reporting that no such seed has ever been tested as his. At present there is probably no other man living in America who is succeeding in raising cauliflower seed. Very likely no other locality is so favorable for the industry. In one of his cold-frames I was shown a single choice head of Wakefield cabbage. This one head is to furnish stock seed for next year. All the seeds it produces are to make heads next year, to be used for seed in 1893. Thus you see how preparation must be made so long ahead for the best kinds of seed. He has three large houses filled with the choicest Golden Self-blanching celery there is, probably, on the face of the earth. I am quite sure there is none in the *world* to compare with it. Ordinary celery is sold for 18, 20, 25, and may be 30 cts. per dozen roots. Friend March gets a *dollar* a dozen, and it is cheap at that. First, he raised a strain of seed that suited him; next, he manured the ground with stable manure and fish guano until the amount of manure under each row suited him. Then he poured on the water until that suited him, and now he gets over *$1000* for the celery that grows on a single acre.

I must not forget a point I got from friend March on the advantage of warm instead of cold spring water for irrigating. After he was satisfied the latter was positively damaging to cauliflower-plants he made his present arrangement for running the water about one-fourth mile in the V-shaped wooden spouts, and then into a storage-tank. The home-made duck hose I have described is attached to this tank. The wooden spouts are supported so high up from the ground that a common wagon easily passes under them the most of the way. The sun and warm air raise the temperature of the spring water to that of the ground by the time it is used for irrigating.

Now a word about his manure: He found on his premises, years ago, a peat-swamp; and every summer, when there is a dry spell, loads of this dried muck are piled under sheds close to his horse-stables, cow-stables, poultry-houses, and, in fact, near all kinds of stock that furnish manure, either solid or liquid, and dry dust is made to absorb every particle. Before spring all the manure is mixed thoroughly, and water enough added to start fermentation. When sufficiently rotted it goes under the rows of celery, as I have explained. In these western regions, when there is a lack of rain in summer time there is an objection to stable manure because it makes the ground dry out quicker, and nothing but plenty of water for irrigation can remedy this, especially where manure is put on in such quantities as market-gardeners use.

GLEANINGS IN BEE CULTURE

A Journal Devoted to Bees and Honey and Home Interests.
Illustrated Semi-Monthly
36 Pages 7×10
$1.00 Per Year.

In the multitude of counselors there is safety.—Pr. 11: 14.

We are having plenty of snow and good sleighing. What effect this will have on the honey the coming season will be seen later.

We regret that we are unable to publish the usual installment of Stray Straws at the head of this journal. They are evidently lost in the mails, as Dr. Miller has recovered from the grip. It was too late to wire for another copy, as we were expecting daily that they would surely come. As it is, we put in a valuable article from J. A. Green in their place.

It is with much pleasure that we publish the presidents' addresses, both of the North American and the Michigan State Bee-keepers' Association. Usually presidents' addresses cover about the same old routine, and everybody is glad when they are disposed of. But these two were decided exceptions. They both call attention to interests that are vital to every bee-keeper, and we hope they will be carefully read.

We are glad to announce that the health of the senior editor is improving. He is not strong yet, by any means, but is doing well. Mrs. A. I. Root met him at San Francisco, as per arrangement, and together they will travel for the rest of their journey. In his last letter he was just on his way to attend the bee-keepers' convention at Los Angeles, Jan. 7. We thought for a time he would not be able to attend this meeting. We presume Prof. Cook, as per announcement, was present also.

We have purchased a lot of large signs, which read: "A. I. Root, Medina, O., Manufacturer of Apiarian Supplies." These signs are to be tacked across the sides of the loaded cars as they come from our factory. Our carloads are now beginning to leave the Home of the Honey-bees; and may be if you are on the lookout you may see some of these signs "skylarking" around the country. There is nothing like keeping your name constantly before the public. See?

On page 18, the per cent of the schedule of the marking of the Italian bee, as reported by the committee at the North American at Albany, does not seem complete. The total footing amounts to only 90 per cent. The committee in their hurry failed to notice it. We would suggest that honey-gathering be made 40, and prolificness 20. This will make the footing correct. Mr. T. G. Newman called our attention to the matter.

It has often been said that bee-conventions, so long as we have such excellent bee-literature, are of no value, except the social feature of them. This is partly true; but some of the most valuable and important questions take root in conventions and give food for further discussion through the bee-journals. We refer to the matter of spraying fruit-trees and poisoning bees, grading honey, etc. A convention of bee-keepers can better protest against injurious legislation than all the bee-journals put together.

OUR book review, on page 952, Dec. 1, of Mr. G. R. Pierce's book, "The Winter Problem in Bee-keeping," has called forth much commendation and corroborative testimony. We are unable to give place to all that has been written on the subject, but we will give something more in our next issue. It seems that others have been experimenting in regard to the use of absorbents versus non-absorbents; and the results of experiments so far seem to justify the use of a sealed cover properly protected with packing. We would suggest, that as many of our readers as can, conveniently, test the two side by side. What might be true of one locality might not be of another. Let us see whether non-absorbents are better—that is, give the best results for all localities.

BRO. NEWMAN, of the *American Bee Journal*, seems to deplore the fact that the matter of spraying fruit-trees, as introduced by Prof. Lintner, at the Albany convention, was not expunged from the records. The mere fact that the professor seemed, for a time, to reject the statement of Dadant and Hambaugh as lacking proof, called forth such *overwhelming* testimonies that neither he nor anybody else could doubt that spraying fruit-bloom is decidedly injurious and destructive to bees. Bee-keepers who have not had experience in the matter of spraying have not been positive that it was a damage to the bees. But Prof. Lintner's skeptical attitude has called forth such overwhelming facts that we for one are glad that the matter came up as it did.

A FALSE ALARM; ADULTERATION OF HONEY, ETC.

ON page 22, Jan. 1, S. T. Fish & Co. state that a certain manufacturing firm to whom in past seasons they had sold carloads of honey, after having experimented with granulated sugar found it far superior to honey, since the article manufactured with honey as an ingredient would sour in time. From this language we gathered that it was a bakery firm, and so stated it editorially on page 31 of the same issue. We have just received a letter from S. T. Fish & Co., stating that it was not a baking concern, but a tobacco firm. They say:

> On page 22 you quote us as having said it was a bakery that refused to purchase honey. Now, we did not desire to mention the line of business in which they refused to handle honey this season, since we thought it of no special benefit to the readers; but since you thought the same ought to be given we will set you right in the matter by stating that it was a tobacco firm. No doubt you are aware that a great deal of honey is used annually by tobacco manufacturers; but whenever fault is found they endeavor to remedy by experimenting; and one factory did this in the belief that the honey had soured the tobacco after it had been in the hands of the jobbers. We explained to them that there is a difference in honey, and we regret that any honey was sold them that should not have met with their entire satisfaction.
>
> Relative to the article from M. H. Tweed, on page 32, we quite agree with him; and while we as sellers can not place ourselves in a position open to criticism, we have no doubt that you would be in a position to find more than two firms in the West who make a business of adulteration. We are not of the opinion that you could gain any thing by publishing them; but whenever it is decided to take any action, and we are consulted, we believe we can give you considerable information.
>
> Chicago, Ill., Jan. 8. S. T. FISH & CO.

We shall be very glad to avail ourselves of your assistance in ferreting out this matter of adulteration. The editor of the *American Bee Journal*, who is also manager of the Bee-keepers' Union, of your city, Mr. T. G. Newman, 199 East Randolph St., is the one the most competent to deal with the matter. We suggest that you confer with him at an early day in regard to it.

SNOW, AND ITS RELATION TO THE FAILURE OF THE HONEY CROP.

WHILE we were sitting at the table in the hotel at Grand Rapids it was our pleasure to make the acquaintance of Mr. A. J. Pierce, whose name we have referred to in our convention report. In speaking of the past four or five years of almost total failure in bee-keeping in Michigan, he gave it as his opinion that it was owing to the lack of snow in winter. He believed that it was necessary to preserve the young clover, and also to give it sufficient moisture for its best development. We had never thought of this before; but, as nearly as we can recollect, there has been rather a scarcity of snow for the last three or four winters, in regions where bee-keeping has been almost a total failure. There was no snow last year—at least, none of any account, in Michigan, and a poor season for bees followed. In York State and Vermont last winter they had very heavy snows, and through all that section of country they had a good year for the bees. It might be interesting to have some statistics prepared, to see what relation there is between snow and poor honey years. Possibly there is no relation at all; and what seems to point that way may be only a mere coincidence. Perhaps some of our readers may be able to furnish us some statistics or facts as to whether winter snow has any bearing on the matter.

REPORTS OF BEE-CONVENTIONS IN THE DAILY PAPERS; A NEWSPAPER REPORTER'S VERSION OF ONE OF THE ESSAYS READ AT GRAND RAPIDS.

ON page 45, current issue, President Elwood, in his address, makes an excellent suggestion, to the effect that the secretary furnish newspaper reporters reliable matter for their papers. It is very well known that they do sometimes make ridiculous bungles, and some bee-keepers have been too much disgusted to even turn their hand over to help them. The reports that appeared in the daily papers of Grand Rapids, of the Michigan convention, were very good as a whole; but to show how even the best of reporters do sometimes get things mixed, we will give you an illustration. In our essay on the subject of "Bicycle vs. Horse for Out-apiary Trips" we incidentally referred to the fact that we had on this machine visited bee-keepers in localities in New York State where there were thousands of colonies. In another part of the paper we had referred to the use of the bicycle in visiting out-apiaries, and told how we had gone seven miles to the yard, and returned. Well, how do you think the reporter got it? We failed to secure a copy of the paper for our own use; but as we remember, it was something like this: "E. R. Root has used the bicycle to good advantage. On it he has gone seven miles into York State, and visited thousands of apiaries. He thought the bicycle a good thing for the bee-keeper." A bee-keeper would natually think that apiaries must be pretty thick along that *seven-mile route* in York State, or else that we were greatly given to exaggeration. It's too bad it is not true, for here would have been a grand chance for the advocates of bee-legislation, or priority of location. The reporter had doubtless heard us use the word "thousand" as referring to colonies, and, as nearly as he could recollect, it was *thousands of apiaries.* Whew! This is worse than Alley's version of the North American. We would suggest the propriety of each one, who prepares an essay or paper for convention, writing out a brief digest of it—yes, two or three of them, to hand to reporters. They will appreciate the favor, and will be glad to give a correct version. It is the fault of bee-keepers, not of the reporters, that such garbled notes appear in the daily press. Bee-keepers should avail themselves of the free notices in regard to our conventions; but let us by all means have correct reports.

M. H. HUNT'S NON-BURR-COMB FRAME.

AT the Grand Rapids convention Mr. M. H. Hunt exhibited his non-burr-comb frame. It is a double top-bar, with a bee-space between, and is the same as that suggested by I. H. Ames, Hudson, Mich. (GLEANINGS, p. 204, 1890). with this difference: The upper bar is only ⅞ inch wide, to give plenty of room to the fingers in handling. The lower bar is 1⅛ wide. This. he says, is an absolute prevention of burr-combs, and we do not doubt it. When the matter originally came up, you will remember we were quite enthusiastic on this double top-bar. It answers the purpose of a Hill device in winter, and also allows the enamel cloth to lie flat, and to be sealed on the frames for winter—a very desirable desideratum, by the way. The reason we preferred the thick top-bar was because it is cheaper, and there are fewer pieces; and, barring the Hill-device feature, it was every way as good. Another difficulty with the double top-bar was the trouble of putting in a suitable comb-guide. As Mr. Hunt wires on the perpendicular plan, a comb-guide is unnecessary.

GRADING HONEY.

ON the first page of this issue, J. A. Green offers some good suggestions on grading. Before reading his article, however, our idea was to use the Chicago system as the basis, calling the first grade "Fancy;" second grade "A," and the other grades by the letters of the alphabet in their order. The Chicago scheme of leaving out *color* as a quality in each grade, we thought a good one, leaving the matter of color to be decided entirely by the *kind* of honey. For instance, a fancy buckwheat could come under the highest grade; but the name "buckwheat" would describe a dark honey. But perhaps there is a difficuly here. The general public, and many of the commission houses, probably would not know what is meant by "Fancy" or "A" grade smartweed or Spanish-needle honey; and they would be utterly in the dark as to what would be their respective colors. The trade call all white honeys clover; that is, it prefers to do so, as its customers are not acquainted with the many sources; but when a honey is described as "white," it has some significance. On the whole, then, we would indorse Green's system. It seems to be an improvement on both the Chicago and Albany classifications. We should be glad to have this subject discussed further. It would be a great boon to bee-keepers and honey-merchants if a *national* system of grading could be adopted. It should be broad enough to be free from local interests, and yet be specific enough to cover every sort of honey.

HEAVY VS. LIGHT BROOD FOUNDATION.

MANY of our readers, in anticipation of sending in their orders soon to their supply-dealer, are debating the question whether they shall use heavy or light brood foundation. We have formerly given the advice that, where frames were not wired, to use the heavy brood. As the horizontal plan of wiring described elsewhere is so cheap, and so little labor, every one will find it cheaper and vastly more satisfactory in its results to purchase medium or light brood foundation, and wire, than to purchase the heavy article and not wire. There are a good many bee-keepers who think it is unnecessary to wire; but we fancy that, if they knew they could wire and yet get good combs for *less* money they would do it. While in this connection, we might remark that a certain German supply-dealer is ordering all his foundation-mills made for extra heavy brood foundation. The walls are so deep that the foundation is ¼ inch thick. We have tested this foundation; and while it makes beautiful combs, it is an awful expense. Only about three Langstroth sheets to the pound can be obtained; whereas, of the light brood there are about eight sheets. With the ordinary heavy brood there are from four to five. With these figures before you, considering that light brood costs only six per cent more than the heavy brood, with nearly twice as many sheets to the pound, the reader can figure out for himself which foundation he prefers. It is immaterial to us or to any manufacturer which grade the bee-keepers order. We do, however, want them to look after their own interests.

SUCCESSFUL MAILING OF 12 QUEENS TO AUSTRALIA.

ALONG last September we sent by mail some thirteen queens to different parties in Australia. The reports are now in, and show that twelve of the thirteen arrived alive, and eleven are now successfully introduced. We make extracts from the letters, that will speak for themselves:

> The queen you ordered from G. M. Doolittle arrived safe with six workers alive. R. J. CRIB.
>
> Brisbane, Queensland, Sept. 22.

> I am glad to inform you both queens came through in tiptop condition. They arrived here, and were safely introduced Nov. 14th. You can mention the fact in GLEANINGS, stating that Mr. Bell, of Brisbane, received and safely introduced the queens on my behalf. S. H. BATEMAN.
>
> Redland Bay, Aus., Nov. 22.

> You will be pleased to hear that the three Italian queens mailed by you Oct. 8 were received Nov. 10 all alive and in good condition. In one cage there were two dead workers; in another, six; and in the other, thirteen. They had consumed in each case about two-thirds of their food; and although they were received and introduced in cold wet weather, I was successful with them all. THOMAS DIXON.
>
> Masterton, New Zealand, Nov. 28.

> The queens arrived here on the evening of Nov. 14, so that they were 37 days coming. Two out of your three arrived in good shape; the other one (bees and queen) had seemingly been dead a long time. Out of friend Doolittle's three, only one (queen and two bees) arrived alive, and the queen died in the introducing-cage a few days after. I may say that I lost one of yours in introducing, so that I have only one left out of the six.
>
> Lyndhurst, Victoria, Nov. 25. JAS. MCFARLANE.

> I am happy to be able to inform you that the three Italian queens arrived here quite safe on Saturday, the 14th inst. The only living bee in one of the cages was the queen, and in one of the other cages there were seven alive besides the queen, and in the third one there were only three bees dead, and they were stuck in their food, and that was the cause of most of the deaths, I believe. As soon as they arrived I introduced them by caging them on the comb, as per instructions in the A B C, and yester-

day they had gnawed out and were laying, and, to all appearance, in the best of health; so, in a short time I expect to have all my black queens replaced with yellow ones. I am inclined to believe in the Italian breed. GLEANINGS has a very wide circulation through all the colonies, and no doubt plenty of your readers would import largely from you in queens, only they are afraid of the risk; but if they send about August they will get the queens out in November. That is just the right time to introduce them; and the fact of three out of three being landed in Dubbo to me will show that there is little or no risk in importing them. C. PEARCE.

Dubbo, N. S. W., Nov. 17.

It seems Mr. Doolittle didn't have quite the success we did. It is possible his candy was not just right; but he will get the knack of it if any one can. As it is, we can say unreservedly that the mailing of queens across the ocean, even to half way around the globe, is no experiment, but a success. Our method of preparing the mail packages was described in detail in our Dec. 15th number, page 970.

THE LOS ANGELES CONVENTION.

JUST as we go to press, a note from A. I. Root, addressed to the "folks at home" comes to hand. As we have had many inquiries regarding him, and the condition of his health, we make an extract from the letter, which answers for itself.

The convention is over, and we have had a most splendid time—not a breath of discord. I wanted to write up notes of it; but Prof. Cook makes a vehement protest. He says that, if I don't stop working every day and hour, I shall be little better off here than at home. He advises an apiary out in some of these mountain ranches, and says that, with Mrs. Root to take care of me, I might live to a good old age. Well, I am going to live to a good old age any way, if I continue to eat and sleep as I do now.

While there is little probability that the senior editor will establish an apiary in California for his health, Prof. Cook's advice to husband his strength is sound, and the Roots, big and little, add their hearty indorsement.

OHIO bee-keepers should remember that the State convention meets this year at Cincinnati, Feb. 10 to 12, at the West End Turner Hall, on Freeman Avenue. It is especially desired that those who expect to attend send their names to the secretary, S. R. Morris, Bloomingburg, O. The fact that Charles F. Muth is president is a guarantee that the arrangements at Cincinnati will be complete. Mr. Muth desires us to invite also the bee-keepers of Kentucky and Indiana, as the place of meeting is on the border of three States.

THOSE of our readers who are poultrymen will take great interest in reading the senior editor's notes of travel, especially where he speaks of his visit to H. A. March's.

CIRCULARS RECEIVED.

The following parties have sent us their price list for 1892.

The Berlin Fruit-box Co., Berlin Heights, O.

The St. Joseph Apiary Co., St. Joseph, Mo.

G. B. Lewis & Co., Watertown, Wis.

S. F. & I. Trego, Swedona, Ill.

We have just printed for Colwick & Colwick, Norse, Bosque Co., Texas, their annual catalogue of supplies for the apiary. Early queens a specialty.

John Nebel & Son, High Hill, Mo., open the campaign of 1892 by issuing a neat catalogue of apiarian supplies which the friends will do well to send for. Printed at this office.

We have just printed the annual apiarian catalogue of Ch. H. Thies, Steeleville, Ill.

J. B. Mason, Mechanic Falls, Me., is now ready to mail to his friends his annual catalogue of bees, queens, etc. Printed at this office.

We have just printed a mammoth edition of A. T. Cook's garden-seed catalogue for 1892. It is a curiosity. Send for a copy. Hyde Park, Dutchess Co., N. Y.

CONVENTION NOTICES.

The Ontario Co. Bee-keepers' Association will hold its third annual meeting in Canandaigua, N. Y., Jan. 30, 31.

[illegible] TAYLOR, Sec.

The seventeenth annual convention of the Vermont Bee-keepers' Association will be held in the parlors of the Addison House, Middlebury, Vt., Jan. 27, 28. Programs mailed on application to the Secretary, Marcia A. Douglas, Shoreham, Vt.

The 12th annual convention of the Northeastern Ohio, Northern Pennsylvania, and Western New York Bee-keepers' Association will be held in Ashtabula, O., Jan. 27, 28, in the parlor of the Hotel James. A good program is prepared. The question-box will be a prominent feature. Programs will be sent to all who desire them. All are invited.

GEO. SPITLER, Sec., Mosiertown, Crawford Co., Pa.

The Minnesota Bee-keepers' Association will meet in Owatonna, Minn., on the 20th and 21st of January, 1892. Free entertainment will be provided for those attending by the citizens of Owatonna, and it is expected that the railroads will carry, at reduced rates, those attending. The State Horticultural Society holds its annual meeting at the same time.

Redwing, Minn. W. DANFORTH, Sec.

The Ohio State Bee-keepers' Association will hold its next annual meeting at the West End Turner Hall, Freeman Ave., Cincinnati, Feb. 10 to 12, 1892, beginning at 10 A. M. on the 10th. All local associations should endeavor to meet with us or send their delegates. Those intending to be present will please send their names to the secretary at their earliest convenience. The president, C. F. Muth, will endeavor to get reduced railroad rates, and reduced rates at hotels. The program will soon be issued, and all particulars published.

Bloomingburg, O. S. R. MORRIS, Sec.

SPECIAL NOTICES.

ALSIKE CLOVER SEED ADVANCED.

In order to get some choice alsike to fill present orders, we were obliged to pay more than the advertised price in our list. Counting bags and freight, it cost us about $10 a bushel; and as the demand for this seed is very stiff we should not be surprised to see it go still higher; therefore for the present our prices will be as follows, bags included: 1 lb., 25c; 1 peck, $3.20; ½ bushel, $6.10; 1 bushel, $12.00. If any of our readers have any choice seed to sell, we should be pleased to have them submit samples, and we will write you what we can afford to pay for it. We can also pay a higher price for Japanese buckwheat than we have been offering. Anybody having any to sell will please send us a sample, saying how much they have, and we will make offers.

1890 PATTERN DOVETAILED HIVES ALL GONE.

The thousand old-style Dovetailed hives offered in this column six weeks ago have all been disposed of. We are prepared, however, to furnish you with all you can use of the latest improved hives at catalogue prices, with 3 per cent off for orders this month. It may not be out of place in this connection to say that we have added quite a number of improvements to this hive since we first introduced it three years ago in March. In this less than three years it has become so popular that it bids fair to eclipse any thing before it in the hive line in point of sales. The demand for it is so universal that, practically, all the dealers and manufacturers are offering them for sale. As we are the pioneers in its introduction and improvement, it would seem as though you stood a better chance of getting the latest improved hives by buying of us or one of our dealers. Joseph Nysewander, Des Moines, Iowa; Barteldes & Co., Denver, Col., and Colwick & Colwick, Norse, Bosque Co., Texas, are supplied with our latest hives in carload quantity. We expect to ship very soon to supply F. L. Possen & Co., Portland, Oregon; Jno. Nebel & Son, High Hill, Mo.; Oliver Hoover & Co., Riverside, Pa., and our eastern branch at Syracuse, F. A. Salisbury agent. Besides these, and others who buy in carload lots, there are many others who buy in less quantities to sell again. To all regular dealers who will handle our supplies we make special terms and inducements, sent only to those who apply.

Cash for Beeswax!

Will pay 25c per lb. cash, or 28c in trade for any quantity of good, fair, average beeswax, delivered at our R. R. station. The same will be sold to those who wish to purchase, at 31c per lb., or 35c for *best selected wax*.

Unless you put your name *on the box*, and notify us by mail of amount sent, I can not hold myself responsible for mistakes. It will not pay as a general thing to send wax by *express*.

A. I. ROOT, Medina, Ohio

CAMERAS CHEAP.

By the death of a relative, as explained in another column, I have come in possession of two very fine photographic cameras. One of them is a Hawkeye, 4x5, with a jointed tripod. It has three dry-plate holders, and three cut-film holders. Besides this, it has a lens that cost originally $35.00, with a triplex Prosch pneumatic shutter worth $10 more. The whole outfit cost originally about $75. The camera-box has been newly finished, and looks like a brand-new instrument. It will also take a roll-holder when desired. I will place my guarantee upon the instrument as being first-class in every respect. It has a far better lens than the average Hawkeye camera. Samples of the work will be mailed upon application. Desiring to give immediate returns to the family of the deceased, I offer this camera for $35 cash. It is a bargain for some one who desires something really fine in this line. Speak quick if you want it, as it will probably be snapped up. I would, under no circumstances, let it go; but, as I have already said, I have two or three other good cameras of my own.

CONVENTION NOTICES.

The Ohio State Bee-keepers' Association will hold its next annual meeting at the West End Turner Hall, Freeman Ave., Cincinnati, Feb. 10 to 12, 1892, beginning at 10 A. M. on the 10th.

The following is the program:

Report of secretary, and routine business, 10 A.M., Feb. 10.

First day, 1:30 P.M.—Essay by Miss Dema Bennett, Bedford, O. "Taking up bee keeping in a general way, and managing the apiary."

Discussion—Which is better for the present bee-keeper—that the number of bee and honey producers be increased or diminished?

7 P.M.—What is a standard section?—Dr. C. C. Miller, Marengo, Ill.

Discussion—How can bees be helped artificially, so that the apiarist will be benefited financially?

Second day, 9 A.M.—Essay by G. W. Demaree, Christiansburg, Ky. "How to prevent swarming during a good honey-flow?"

Discussion—Are absorbents important?

Grading of honey, and bounty thereon.—H. R. Boardman, East Townsend, O.

1:30 P.M.—Packing bees for outdoor wintering.—E. R. Root, Medina, O.

Discussion—Is top ventilation preferable to bottom ventilation during the winter months?

7 P.M.—Paper by Dr. A. B. Mason, Auburndale, Ohio. "Foul brood."

Are closed-end bars of brood-frames preferable to ones?—Dr. G. L. Tinker, New Philadelphia, O.

Third day, 9 A.M.—Discussion—Is honey-dew injurious to bees as a winter feed?

Are artificial swarms less vigorous than natural ones?—O. A. Corey, Frankfort, O.

Discussion—Are bees injurious or are they beneficial to grapes and fruit in general?

Music will be interspersed each day as convenient.

RAILROAD RATES.

The Central Traffic Association of Chicago has agreed to give us 1⅓ fare on all roads leading into Cincinnati, providing we have 100 persons in attendance. Everybody buying a ticket to Cincinnati should ask the agent for a certificate for the convention. This certificate, signed by Sec'y Morris, may entitle the holder to a one-third fare home. It positively will not, if less than 100 tickets are sold, on all branches of the Cincinnati, Hamilton & Dayton Railroad. Hotel rates will be announced at the convention.

Bloomingburg, O. S. R. MORRIS, Sec.

SPECIAL NOTICES.

ALSIKE CLOVER SEED.

We have secured a choice lot of seed since our last, in such quantity and at such a price that we can offer it at the following price till farther notice: 25c per lb.; by mail, 34c; $2.80 per peck; $5.50 per ½ bushel; $10.50 per bushel, or 2 bushels for $20.00, bags included. The time for sowing this seed is near at hand, and we regard it a safe investment to secure your seed at these prices, as it is almost sure to be higher later in the season.

ROOT'S GOODS FOR THE EAST.

Bee-keepers of New York, Vermont, and the East should bear in mind that we have established at Syracuse an Eastern branch where our staple bee-keepers' supplies are kept for sale and prompt shipment. You can save time and freight by ordering from our Eastern branch. We have engaged Mr. F. A. Salisbury to take charge of this business, and he will treat you well. Address all orders, Eastern Branch, F. A. Salisbury, Agent, 1635 Genesee Street, Syracuse, N. Y.

SEED POTATOES.

We would call special attention to our list of seed potatoes. We have a fine stock of all the varieties we advertise. You will notice our list comprises from the earliest to the best of the medium late. The very latest kinds are so much more expensive to raise, on account of the long time they must be cared for, that we do not advise anybody to bother with them, especially in view of the splendid edible qualities of the Puritan and Monroe Seedling. This idea will be better appreciated when it is considered that the Monroe Seedling, Lee's Favorite, and even the Puritan, will, if planted about the first of June (in this region), keep until new potatoes come again.

TO THE FRIENDS OF THE GARDEN.

We wish to apologize for being a little later than usual with our seed catalogue. We are so well pleased with the selection of varieties we offered last year, and our customers report such good success with them, that we make comparatively few changes in the kinds. We offer our friends better seeds this year than we ever have before. The most of them are our own raising, and saved only from carefully selected stock. The new catalogue will be out in a few days now; but if you are in a hurry for your seeds, send on your order; we will fill it from new stock just the same, and send you a new catalogue as soon as they can be got ready. There are a few changes in prices also. Some things do not cost so much as last year, and, owing to failure of crops, and our determination to furnish only the best of seed, a few things will cost a little more. We have a nice lot of plants started and will be ready to ship as soon as the weather will permit. We can ship cabbage-plants, asparagus roots, and potatoes to the South between blizzards if our friends want them right away.

My 654 Colonies of Italians

Are wintering well, and, as usual, I will sell a limited number of them to reduce stock to the required number. Each hive shipped to my customers will contain a full prosperous colony of Italian bees, with a last year's tested queen, on eight Hoffman frames of brood and honey. As my main object in handling bees is honey, we raise all our queens in full colonies from cells built under the swarming impulse, using the choicest and most profitable stock to breed from.

Safe arrival guaranteed in May and first half of June. For terms please address

T. PHILLIPS & CO.,
3-5d *ORILLIA, ONTARIO, CAN.*

THE JANUARY REVIEW

Is now out. It contains articles from W. F. Clarke, and Ernest Root, upon "Writing for the Bee Journals." R. L. Taylor shows how much it costs, or *ought* to cost, to produce comb honey. Mr. S. Corneil explains how, with but little trouble and expense, any one may know if his bee-cellar is too damp. R. C. Aikin furnishes a long, interesting account of "Colorado, its Soil, Climate, and Alfalfa Farming, and how the latter furnishes Honey." The inimitable Hasty begins in this issue what is to be a series of articles entitled: "Comments on a Beginner's Day-Book." This "Day-Book" was kept by Mr. Hasty when he first began bee-keeping. E. T. Flanagan tells how he has bridged over poor seasons. Most of the articles are embellished with a portrait of the author. There are the usual extracts and editorials, including an account of the trip to Albany, and a "leader" upon the special topic for the February issue, viz., "Grading Honey." If you would like to see this number, send ten cents, and with it will be sent the December number; and when the February number is out, that too will be sent. The Review is $1.00 a year. The book, "Advanced Bee Culture," is 50 cts. Both for $1.25. All new subscribers for 1892 will receive the December, 1891, issue free. Address

BEE SUPPLIES RETAIL —AND— WHOLESALE.

Everything used in the **Apiary.** Greatest variety and **largest** stock in the West. New catalog, **54** illustrated pages, free to bee-keepers. **E. KRETCHMER, RED OAK, IOWA.**

In writing advertisers please mention this paper.

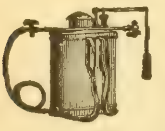
FOUNDATION **AND SECTIONS** are my Specialties. No. 1 V-groove Sections at $3.00 per thousand. Special prices to dealers. Send for free price list of every thing needed in the apiary.
2tfdb M. H. HUNT, Bell Branch, Mich.

☞In responding to this advertisement mention GLEANINGS.

1892 CIRCULAR READY TO MAIL YOU, FREE. Dovetailed hives, Sections, etc. LATEST IMPROVEMENTS in hives and frames. **Discounts** for early orders.
1tfdb **JNO. NEBEL & SON, High Hill, Mo.**

POULTRY. Choice Fowls and Eggs for sale at all times. Finely illustrated circular free. GEER BROS., St. Marys, Mo. 21tfdb

Send for Price List to
R. E. HARBAUGH,
Manuf'r and Dealer in Bee-Keepers' Supplies.
Breeder of Italian and Carniolan Bees and Queens, Light and Dark Colored Ferrets.
25th and Clay Sts., - - - St. Joseph, Mo.



SPRAY YOUR FRUIT TREES AND VINES

Wormy Fruit and Leaf Blight of Apples, Pears, Cherries, Grape and Potato Rot, Plum Curculia prevented by using EXCELSIOR SPRAYING OUTFITS. PERFECT FRUIT ALWAYS SELLS AT GOOD PRICES. Catalogue showing all injurious insects to Fruits mailed free. **Large stock of Fruit Trees, Vines, and Berry Plants at Bottom Prices. Address WM. STAHL, Quincy, Ills.**

24-10db ☞In responding to this advertisement mention Gleanings.

Porter's Spring Bee-Escape.

We guarantee it to be the best escape known, and far superior to all others. If, on trial of from one to a dozen, you do not find them so, or if they do not prove satisfactory in every way, return them by mail within 90 days after receipt, and we will refund your money.

PRICES:—Each, by mail, postpaid, with full directions, 20c; per dozen, $2.25. Send for circular and testimonials. Supply dealers, send for wholesale prices.

10tfdb *R. & E. C. PORTER, LEWISTOWN, ILL.*

GLEANINGS IN BEE CULTURE

A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS

ILLUSTRATED SEMI-MONTHLY

PUBLISHED BY A. I. ROOT.

$1.00 PER YEAR MEDINA OHIO

Vol. XX. FEBRUARY 1, 1892. No. 3.

STRAY STRAWS

FROM DR. C. C. MILLER.

DOOLITTLE is to talk bees in the New York *Voice*. He'll have a big audience. They'll have a good man.

THE *British Bee Journal* thinks Messrs. Alley and Pratt are somewhat changeable in their views about Carniolans.

WILL FRIEND DRAPER please tell us *why* "comb-honey production doesn't need it," if extracted honey needs a two-cent bounty?

LA GRIPPE! La Grippe!
You old rip,
How you sip
The very life out of a body!

AUTOMATIC SWARMING-DEVICES (p. 58) were discussed at the Michigan convention. I don't need any swarming-device. My bees swarm too much now.

DOOLITTLE, bees *do* hibernate. I know yours don't, neither do mine; but the kind that work wax with their stings as trowels hibernate any cold night.

RAMBLER takes the "we" and "I" business hard. Even in his dreams it troubles him. Wonder if it's a bad conscience, or if they fed him something wrong at Dowagiac.

THE *Review* has struck out in a new line by giving at the head of each article a picture of the writer. Some of the likenesses are excellent; but mine was taken when I was bad with the smallpox.

TELL A. I. ROOT that they are sending around some of that lumber he saw in Oregon where it will do most good. My house was covered last fall with red-cedar shingles from Oregon. They cost, but they last.

SOMEBODY must have read my paper crooked at Albany to make me object to 4¼x4¼x1⅞ sections. Why, I'd rather have *all* 4¼ sections so thin that no one could be cheated into buying one for a full pound.

THE BIG NEW YORK BEE-MEN, we are told on page 21, are shy of reporting their crops, for fear of some one crowding in on their territory. Wonder if they would object to having legal control of their territory.

NAPHTHALINE is reported in *B. B. J.* as a cure for asthma, and also for whooping-cough. For asthma, a smell of the drug before going to bed, and for whooping-cough the room to be filled with the fumes from ¾ of an ounce placed on a hot metal dish.

EXACTNESS is important in all bee-fixtures, as a general rule. Now, there is one thing that often nullifies all efforts at exactness—warping. Before me is a piece of beautiful workmanship; one piece, however, $\frac{7}{16}$ thick, has warped $\frac{3}{16}$ out of true, and a piece an inch thick shows warp plainly. Can Mr. Warner or any one else tell us the secret of selecting lumber that will not warp?

A. I. ROOT better come home and see to those boys. They've gone and painted the cover of my last GLEANINGS another color, so I didn't recognize it when I took it out of the postoffice. I like the change, though. May be they'll give us a different color each year, so we can tell at a glance to what year any number belongs.

GEORGE WASHINGTON "couldn't tell a lie." I'm different—I can. But I won't. And the plain truth is, that the installment of Stray Straws for the Jan. 15th number of GLEANINGS was not lost in the mail, but was gently reposing in the pocket of my second-best coat, where I had forgotten them. Moral—Don't have more than one coat.

ADAM GRIMM showed me a cellar that he had just built, with a cement bottom, with which he was pleased, but on trial he found it a failure. I had a cement bottom purposely made for bees, but don't use it. Bees winter better in the part not cemented. Before building a new cellar, "A" (see p. 26) might try tearing out his cement floor.

THE HONEY FAILURE is laid to the weather by Hon. R. L. Taylor, in *Review*. He proposes to remedy the matter by dosing the weather with condition powders. I have no faith in such a thing, and warn all bee-keepers not to buy of him. He is a good law-maker and a good bee-keeper, but has no regular medical education. If your weather is out of order, send $1.00, with description of weather, to Dr. Tinker or me.

THE SPACE below frames, two or three inches deep, for winter, is a "pet notion" with the *B. B. J.* That shows that the *B. B. J.* is wise in its selection of pets. As proof of the benefits other than prevention of clogging, the editor says, "What bee-keeper of experience has failed to notice how well second swarms, which have only half filled their hives with combs, will winter, and how healthy and vigorous they will be in spring?"

FEEDING SUGAR to produce honey, in the shape of the Wiley lie, has kept us fighting for years; and now comes a correspondent of the *Review* and gravely raises the question whether, in bad seasons, we may not have good comb honey made by feeding sugar in the right way and at the right distance. The Wiley affair was an attempt at murder; the present effort, coming from one of our best men, in one of our best journals, is an attempt at suicide.

I'M BEGINNING to get mad. There's so much said nowadays about "handling hives more and frames less," and now Hutchinson says that the use of frames is to have us learn the mysteries of the hive, and, "having in a large degree mastered these, there is little need in practical bee-keeping to handle combs." Now, I'd like to handle frames less, but I don't want to handle hives "more." If W. Z. is right, we can learn the mysteries from books, and keep box hives.

THAT NUT of Mrs. Null's on page 25. Struck it wrong, and hit your finger instead of the nut, sister Null. Why, bless your heart, the nut's all right, and there's a good meat in it. So far as I know, Missouri has beaten all other States in getting up a large State society at the start, and it's only because I'm not handy in the use of the English language that I didn't properly express the admiration that I really felt. I think the start made is "pretty good" for any State, even such a central State as Missouri. Now we're friends again, aren't we, Mrs. Null?

BOUNTY ON HONEY.

IS IT DESIRABLE OR FEASIBLE? DO SUGAR AND CANNED FRUIT COMPETE WITH HONEY?

The matter of making an effort to secure a bounty on honey was lightly discussed at Chicago, and it also came up at Albany. The editor, on page 13, seems anxious for light as to its desirability and feasibility. Perhaps it might be better to discuss its justice and feasibility, although, in the highest sense, if it is not right it is not desirable. Unless there is both justice and feasibility, it is not worth while spending time talking about it. If there is justice in the case, I have no great doubt as to feasibility. The simple fact that justice demands a bounty, ought to be enough to secure it. Still, it is not always enough. But I think a sufficient amount of united effort would be effectual.

Therefore, before discussing how we are to obtain a bounty let us first settle conclusively that we *ought* to have it. To say that I should like it is one thing; to say that of right I am entitled to it is quite another. As a premise in the case, we may start out with the fact that a bounty of two cents per pound has been granted to sugar-makers. The truth of its accomplishment is a strong argument as to its being a righteous act, and indeed I do not know that its righteousness has been called in question, although I am not politician enough to know.

Granted, then, that sugar has a right to the bounty, can honey make the same claim? I believe the argument in favor of sugar is, that, when the tariff on sugar was lowered, it let in foreign sugar at a so much lower rate that the home product could not successfully compete with it, and for the sake of encouraging the latter the bounty was allowed. Whether that argument will bear the closest scrutiny I am not prepared to say; but, admitting its correctness, will it, or will it not, apply with equal force to honey? If it can be established that there is competition between sugar and honey, then I can see no reason why the same argument that applies to domestic sugar will not apply to honey. Indeed, if there is any difference, the argument for honey is a little stronger than for sugar, always provided that sugar competes with honey. For, by a direct act of government, sugar has a bounty of two cents per pound, thus giving it an advantage of two cents per pound over honey, whenever the two come in competition. Therefore justice demands that the injury done to the honey market, by putting it in competition with the bountied sugar, be righted by a compensating bounty on honey. The only question in that case is whether the bounty should be two cents per pound, or proportionally greater according to the relative values of the two products. Possibly it should be somewhat according to value. That is, if honey is 50 per cent more than sugar in price, then the bounty on honey should be 50 per cent more on honey, or three cents per pound. But that can, perhaps, not be claimed, for it would be replied that a dollar's worth of honey does not compete with a dollar's worth of sugar, but that a pound of honey competes with a pound of sugar.

Now, let us see how far we have got. If there is no leak in my logic, we have about settled that, if sugar is entitled to a bounty, and if sugar competes with honey, then honey is entitled to a bounty. Now let us consider the question as to whether the price of sugar has any effect on the price of honey; in other words, whether the two are really competitors. Before having written thus far, I spent some time thinking over the problem, and it occurred to me that one who used considerable quantities of both would be a proper person to help decide how far they can be considered competitors. So I went down to the sitting-room, where my wife sat sewing, and, after telling her that bee-keepers were agitating the question of a bounty on honey, I said, "I hardly know which side of the question I am on." "But," said she, "the chance for rascality in claiming a bounty on more honey than has been raised, just like the dishonesty in the pension business!"

"Oh! that has nothing to do with the question in hand," said I, a little nettled at the insinuation that there were dishonest men among bee-keepers. Then, after sitting for a little time looking at the glowing anthracite in the Howe ventilator, I said, "Does the price of sugar have any thing to do with the amount of fruit that is put up, or used for sauce?"

"Oh, certainly! a great deal to do with it."

"What has it to do with it?"

"Why, if sugar were, say, a half higher than it was this year, I wouldn't have put up nearly as much. Get along with less—that's all."

After studying the coal fire a little longer, I asked, "Does the amount of fruit sauce or canned fruit make any difference as to the amount of honey used in a family?"

She answered, somewhat slowly and hesitatingly, "Why, I should think it would." Then in a more decided manner, "Yes, certainly it would." Then, after sewing a few moments in silence, she added, "Because, when you have those things you don't care so much for honey." After sitting a minute, I said, "As it looks to me now, I'm in favor of the bounty," and then went back up stairs.

My wife's view of the case looks reasonable, and she speaks from experience. Grocers have also told me that, when fruit was scarce, honey sold more readily, and vice versa, showing that a diminution in the amount of fruit sauce used helps the sale of honey. Of course, if the high price of fruit helps the sale of honey, so would the high price of sugar, for either one would make the sauce more expensive.

I think it is a very clear case that molasses and syrups are in competition with honey, but I'm not so sure that the prices of these are directly affected by the price of sugar. But where the syrup is home-made, simply melted sugar, as it is often used on hot cakes, then the competition is evident.

Supposing that it may be clearly shown that the allowance of a bounty is the correct thing, it is just possible that another question may arise in something like this form: "Will a bounty, in the long run, be a benefit to the producer, or will it be only to the consumer?"

Marengo, Ill., Jan. 8. C. C. MILLER.

SUGAR VS. HONEY.

THE COMPETITION OF CHEAP SUGAR, JELLIES, AND OTHER DELICACIES, ON HONEY; DISCRIMINATING LEGISLATION AGAINST THE BEE-KEEPER.

The idea has been several times advanced, in these columns and elsewhere, that cheap sugar does not in any way come into competition with comb honey, and that it is only the cheaper grades of extracted honey that suffer from such competition. I think both of these opinions are fallacious, as a little study of the question will show. People do not usually eat honey simply because it *is* honey. Some eat it simply because it is one of the family of sweets for all of which they have a natural craving. This craving can be satisfied just as well with sugar, or some sweet made from it, as with honey. Generally honey is eaten because it is a palatable table sauce, a pleasant addition to the bread and butter and other articles of food. In this direction it has many rivals.

Did you never, as you sat at the table, hesitate as to whether you would take jelly, honey, or plum preserves? Or, perhaps it was a nice dish of cranberries or other stewed or canned fruit, or any of the long line of similar delicacies that divided your liking. Just as you hesitated, the housekeeper hesitates in furnishing her table, and in making her choice, if she is thrifty and careful—and generally she is; she is influenced largely by considerations of economy.

When honey is plentiful and cheap, she may buy of it freely and often; but when it is scarce and high, as we well know to our sorrow, she selects something else to fill its place. When sugar is cheap she puts up large quantities of fruit, with jams and jellies galore. With all this array of good things upon her pantry-shelves she does not see any need of buying honey, unless very occasionally, just as a change. If she is not of the providing kind her family are not allowed to suffer. In every grocery store she may find a tempting array of jellies and of fruit butters at astonishingly low prices; and since sugar has taken the place of the glucose that was formerly a chief ingredient of very fair quality, the growth of the trade in such articles has been enormous of late, and no doubt will continue.

One has only to visit some of the groceries where they ladle their jellies and fruit butters out of barrels, when, only two or three years ago, a few half-pint tumblers constituted their entire stock of such articles, to realize that here is our most formidable rival.

Honey is called a luxury, and must be so considered; but by comparing the sales at the different classes of groceries I have discovered what seems at first sight a little peculiar. It is not the rich nor yet what are called the upper middle classes that use the most honey in proportion to their numbers, but those who are only in comfortable circumstances, the families of artisans and laborers. The former, with their stores of table delicacies laid up, or readily procurable, have felt no need of buying honey but get it only as the fancy strikes them. The latter, living more "from hand to mouth," must buy such things as they are needed. Often in their search for sweets for the table they have found honey as the only competitor to the sugar and molasses barrels. But with cheap sugar, that is being changed; and a great variety of fruit preparations are for sale at low prices. This competition will, no doubt, be stimulated, and become stronger. We do not perceive its full effects yet, because of the scarcity of our product. But let a large crop of honey be put upon our markets, and we should speedily see to what extent we have been injured by discriminating legislation.

The same influences that affect the sale of comb honey are also operative against the sale of extracted honey for table use. It is in another direction, however, that we have most to fear. Within the past three or four years the use of honey in the arts has been much extended. Now, just as we are congratulating ourselves on the market thus gained, comes the unwelcome news that the cheaper sugar is being substituted for the honey. Now, even though it be true that only the poorer qualities of honey have been thus supplanted, this can not fail to have an effect on the general market. When the outlet has been closed for these grades of honey they must seek a market elsewhere. In doing this they must come into competition with other qualities, and tend to force their prices down. It is said, that no particle of matter, however minute, can change its position without affecting the entire universe. So every pound of honey placed upon the general market must affect in some degree the price of all honey sold. So, too, the government can not interfere with the natural channels of trade in any industry without affecting to some extent all others. In this case we are the ones who are pinched. Of course, we squeal. We ought to. Let the bounty on sugar be removed, or let us receive a bounty and so pass the burden on to somebody else.

The point touched upon by A. N. Draper on page 13 might be an important one if it were true that the government placed its stamp upon all packages of sugar upon which a bounty is paid. If I am correct, it does not do this—certainly not to the extent and with the thoroughness that it does in the liquor and tobacco business. I think that, when the producer furnishes satisfactory proof that he has actually produced a certain amount of sugar, he is paid the bounty, and that ends the matter. I see maple sugar in the stores nearly every day; but there is nothing about it to indicate whether it came from a Vermont sugar-camp or a Chicago mixing-establishment. J. A. GREEN.

Dayton, Ill., Jan. 7.

A GOVERNMENT BOUNTY OR TAX ON HONEY.

REASONS WHY IT WOULD WORK MISCHIEF TO BEE-KEEPERS; IT WOULD NOT HINDER OR PREVENT ADULTERATION.

As the subject of a government bounty on honey has been spoken of in GLEANINGS, and a discussion of the subject invited, will you allow me to say a few words in regard to it, and also comment on what was said on page 13 by A. N. Draper? He refers to the connection of the government with the liquor-traffic as an illustration of how a bounty would help the honey-business. That the laws of the national government foster and make more powerful the liquor-traffic, there is no reason to doubt; but that it hinders adulteration, we know is not true, but just the reverse. By protecting it for the revenue, it creates a vast monopoly; and by taxing the manufacture and sale, it enhances the price more than fourfold, and consequently makes adulteration (when it goes into the retailer's hands) very profitable; when the fact is, that, if it were not for the tax that it pays, the original liquor would not be more than 25 cents a gallon for whisky, and at that price there would be no profit in its adulteration. Then, in order to make the liquor and honey business similar, a tax should be put on honey, and the government could put its stamp on the package to show that the tax was paid; but how is the government to know that every package is pure honey when so much disagreement has been shown among the chemists who have analyzed samples heretofore? Honey is already on the protective-tariff list, and now we would have Uncle Samuel put his hand into other people's pockets and take out their money to give to us so much a pound because we are producing a different kind of article from that which they produce. Our government can not get money except by taxing, directly or indirectly, the people; and every dollar paid as a bounty on sugar is taken from the people as a whole and given to a class who produce sugar. The hundred million or so a year that is the government's share in the liquor-business comes from those who drink it, and, in consequence, hundreds of thousands of poverty-stricken wives and children of drunkards are deprived of food and clothing, and the other necessaries of life, that the liquor-monopolists and its powerful partner, "Uncle Samuel," may fill their pockets, while the great proportion of the remainder of the government's revenue is derived from the consumers of the tariff-protected articles imported into the United States. Now, again, I ask, by what principle of justice can the government put its strong hand into *my* pocket and take my money and *give* to somebody else because he is engaged in another kind of business? I make some butter, as well as produce some honey; and as prices have been for a number of years, I have not netted two per cent on the capital invested, with labor thrown in; please tell me why I should not have a bounty of 5 cents per pound on my butter; and then the men who produce pork, beef, wheat, oats, potatoes, and, in fact, every product of labor, should not have a bounty, for the producers all say, and truly, that they can not make reasonable profits on their business. A man who desires the government to take other people's money and *give* to *him* for no equivalent is either very selfish or else he has not looked the matter over carefully; for it indisputably would be a violation of every principle of justice. Let us use our efforts to get stringent laws passed in all of the States against the adulteration of honey, and then get, if we can, executive officers elected who will not neglect their enforcement; and that is the best we can do. VOLNEY WHITE.

Findley's Lake, N. Y., Jan. 7.

THE OBJECT OF A BOUNTY; WHOM IT BENEFITS.

BOUNTY ON HONEY NOT DESIRABLE.

I notice in the Jan. 1st issue of GLEANINGS a letter by A. N. Draper, taking up the topic of a bounty on honey, and treating from a point of view that might for a while result more favorably in some particulars to the producer of honey. (By the way, an outsider would naturally draw the inference that Mr. D. is a producer of the extracted article, as he says comb honey needs no bounty.) As the question of the bounty on sugar is understood in this part of the country, the bounty is not primarily intended so much for the benefit of the party or parties producing the sugar, though, of course, that is where the benefit first alights; but it is to foster and help the growth of an industry that will be an infinite benefit to the country at large. It is also supposed to act as an inducement to timid capitalists to invest enormous sums of money in factories for working up large amounts of material into a product that the people have been sending their money abroad for in vast amounts for many years past; the idea being kept in sight at all times, that, in a very few years, these plants or factories will not only be self-sustaining, but that they will return the money paid them in bounties by the government much larger sums to the people in the form of cheaper sugar.

Now, honey is not a thing that the country in general considers a necessity, neither is it a thing that they should or would be willing to be taxed to pay a bounty on for the benefit of the producer. Honey-producing is an industry that has been developed pretty extensively for a number of years, and that can stand on its own bottom, with a little assistance in the way of a tariff duty on the imported article, which it already has. He says, further, "Let the government stamp what honey is actually produced in this country, and adulteration will cease;" and likens honey-producing to whisky-producing. Has the government ever paid a bounty on the production of whisky? If so, it was before my time. The stamps affixed to the packages of whisky *cost the producers* of that article quite a tidy sum, and I believe the government does not undertake to certify to the purity or wholesomeness of any package to which the stamp is attached; further, liquors which bear government stamps and inspectors' marks are popularly supposed to be as rank and vile mixtures of adulterators as is possible for them to concoct; at least, so we were taught by the truly good prohibition brethren last campaign in Nebraska, so there falls one of his principal points. So long as learned chemists pronounce pure honey from the bees as adulterated with glucose, as has been done on several occasions, so long must consumers take their chances of a mixture; and so long as a cheaper product can be mixed with the genuine honey, to the financial advantage of the mixer, so long will a mixture be on the market unless we get in force a severe and stringent law punishing the seller of a product that is sold for what it is not.

It is really too bad that Mrs. H.'s chances of a crop are getting a trifle risky at Peoria because her field is covered by a city. It has never been considered a function of the government, however, to assume all risks in the business ventures of its citizens, and guarantee them a profit. I can see only one of two remedies in her dilemma. She might persuade the Peorians to go west and uncover her field, or, failing in that, she might come out, possibly, herself with her bees where we have many broad fields yet uncovered by cities, and we would make either Peoria or Mrs. H. *awfully* welcome too.

I am probably wrong, but it seems to me a good deal disgusting—the howl that is ascending to the skies for something to be given to this class and that. It seems to be getting to be a mania to want to pull at the public teat in some manner. Farmers want government to build them warehouses in which to store their crops; and not only that, but to give them the money for their crops, and hold it till they can starve those needing it into giving all they choose to ask for it. Not only that, but, after the government has given millions of farms to the present owners, they now want the government to let them have the worth of their farms in money without interest, and keep their farms too! Bee-keepers want other people to pay them two cents for their honey, and allow them to keep their honey. Sugar-men want two cents per pound for all the sugar they can make. But here is some return—they sell the sugar two cents per pound cheaper than they did before the bounty was granted, so there the people are nothing out for their liberality, while in a few years there is every prospect of their being largely gainers for their foresight. A bounty on honey would probably have a like effect in the course of a very few seasons, as it would largely increase the supply of extracted, without a corresponding increase in the demand, except at a lower price; consequently the bee-keepers would be in the same fix as now, only with an increased number of producers in the field. The trouble with bee-keepers, as I plainly see it, is, that the publications of the craft are too much interested in getting new blood in the business instead of well beating up the ground that is already occupied. They seem to feel it their duty to attempt to convince every individual with whom they come in contact that it is the rosiest business in the universe, and that their whole duty will not be performed until they become bee-keepers. It is the only trade, profession, or business in the universe that makes constant and vigorous efforts to increase its supply and decrease the demand for the products of its labors. I "am a bee-keeper for pleasure" (and profit); but when I constantly try to get others to start in the business, and begin to shout for a little assistance in the way of a bounty for the honey I produce, I am going to decide there is no fun in the business, and resign. At the same time, if the philanthropists insist on putting into our pockets a few extra dollars as they did for the maple-sugar men (which was an outrage), I am not going to make a heavy kick, but it will be a fraud just the same. C. F. Thomas.

Dorchester, Neb., Jan. 7.

ITALIANS IN ITALY.

THOS. B. BLOW, OF ENGLAND, WHO HAS TRAVELED IN ITALY, SAYS THE BEES IN ITALY ARE NOT UNIFORM AS TO COLOR OR MARKINGS.

Dear Mr. Root:—I have read with interest your note to the letter on Italians in Italy. Now, I know that, of all things, you wish to get at the truth in these matters, and also to show where the advantage or otherwise to the bee-keeper comes in.

As to color, I think far too much stress has been laid upon this. What we should strive after is, rather, working qualities. Bright-colored three-banded Italians are very pretty, and all that; but what the bee-beeper wants is not beauty altogether, but work—honey-gathering. There is no question at all but that plenty of bright-colored, three-banded bees do exist in North Italy, and especially are they found (by selection, of course) in the large apiaries of the queen-raisers. The bee of North Italy does vary a good deal in color, and often is very dark. This fact is well known to those who have studied the question on the spot (and, by the way, one of the persons whom Mr. Bianconcini mentions in his letter as an eminent authority, has, I believe, never been in Italy at all, but has been simply an importer of bees, and is not accepted here as an authority in this particular subject). To my own certain knowledge, at one time Cyprians were used in some of the queen-raising apiaries, with a view to improving the color, though I believe this plan is now abandoned, and rightly too. The best observers in Great Britain are, I think, agreed that the Italian bee, as imported at the present time from many queen-raising apiaries, is quite an inferior article to those sent over in the early days; and to such an extent has this opinion gained ground that the importation of Italians to this country has, to a great extent, ceased.

Another point against them has been the suspicion (well grounded, I believe) that a very virulent form of foul brood has been introduced by them. Of this I think there can be no doubt, as I have personally seen the way that bees were collected in Italy in the autumn, for the sake of the queens, which were simply taken from the colonies (bought from the country people), and packed off wholesale—young or old, diseased or healthy. At that time I wrote and protested against this system, and I imagine that it does not now prevail to such an extent, the business being now mainly in the hands of honest queen-raisers who take some pride in the quality of the article they raise—especially the color of it. My own experience—gained by many visits to Italy—is, that it is not from the largest queen-raising apiaries that we get the very finest bees; and the locality, too, is important, the bees from the higher districts being much hardier than those from the hot plains. I could mention the names of several people who certainly produce only a limited number of queens; but each one is a queen of the right sort. Thomas B. Blow.

Welwyn, England, Dec. 30.

[We must admit that there are some dark bees in Italy; and it is possible that there are some dealers who are unscrupulous in the filling of orders; but the stock that we have received in the last ten or fifteen years from Italy has been from only one or two breeders, and their queens have been of the very best—at least, as a general rule they have excelled our home-bred stock, although there are exceptions to the rule. Whatever may be the bees in Italy, the conditions for rearing queens are better there than in this country—at least, results seem to point that way. We quite agree with you, that it is not the golden-banded or highly colored queens that usually give the best results in the production of honey. As you may know, we have been trying to educate the general bee-keeping public toward procuring queens that are bred for business rather than for color. The leather-colored ones have generally given us the best results. In Italy they have not got the rage for queens for beauty—as least, not to the same extent that they have in this country.]

THE ITALIAN BEE IN ITALY.

IS IT A HYBRID OR SIMPLY A VARIETY OF A WELL-KNOWN SPECIES?

Mr. Doolittle propounded the theory at Albany, and I have also seen it elsewhere in his writings, that "the Italian bee is a hybrid." The meaning of the word "hybrid" is, I believe, "mongrel, or the production of two species." In natural history, by "species" is understood the original type, and the changes produced in that original type by climate and different natural surroundings, are called "varieties."

If by the term "hybrid" Mr. Doolittle means that the yellow Italian bee (I use the word "yellow" advisedly) is a variety of the black, or German bee, it's possible that he is correct, though there are several distinguished naturalists who hold that the yellow bee is the species and the black the variety. But if Mr. Doolittle means that the crossing of the two species is so recent that the type is not sufficiently fixed for the Italians to be called even a variety, I contend that he is wrong; for in its natural locality it has a fixed type that has not changed since Virgil first wrote of the yellow-banded bee, as can be shown by comparing the descriptions of Spinola, who, in 1805, called them Ligurians;

of Dzierzon, who introduced them into Germany in 1853, with that given on page 14 in January Gleanings. That there are changes under different climatic and geological conditions, I admit; and it is to be expected, reasoning from the changes that are common in both animals and plants when removed from their natural home (see page 14 as above).

The original location of the Italian bee, I believe to be the mountain-ranges of Northern Italy and Switzerland; hence Spinola's name, Ligurians. Mr. Woodbury, of Devonshire, obtained the first Italians, imported into England in 1859, from M. Herman, of Samin by Chur, Switzerland, who, in a pamphlet published about that time, says: "The yellow Italian bee is a mountain insect, found between two mountain-chains left of Lombardy and the Rhœtian Alps, thriving up to 4500 feet above sea-level. The Alps are their native country."

This, their home, has very marked characteristics—high mountain-ranges with perpetual snow on their summits, while in numerous sheltered valleys there is almost perpetual spring. Such a district would naturally impart peculiar traits to all its inhabitants; and what wonder if, when transplanted to less rigorous climes, a change, improvement or otherwise, occurs, as emphasized by Mr. Herman in his pamphlet quoted before? "The further one goes from the Alps, the less handsome they are, until in lower Italy they are entirely lost in the black species."

Perhaps here may be found the explanation of A. T. Goldsborough's letter in a recent number; and, to carry the point still further, but in an opposite direction, in more ways than one, turn to page 506 and read what J. P. Israel says of the Italian bee in California. There in the mountains it found a country more nearly approaching its native land than elsewhere in America.

I conclude, then, that, as the points which give the Italian bee superiority over others are due to its natural environment, we shall continually need to import fresh stock from its native Alps to get home-bred queens superior to instead of deteriorating from the natural type.

Avery, La. H. Fitz Hart.

THE SALT REMEDY FOR FOUL BROOD.

WILL IT CURE IF PROPERLY APPLIED?

On page 822, 1890, W. L. Coggshall, of West Groton, N. Y., says: "I have 600 colonies of bees. My experience with bees has taught me that, as soon as they begin to fly in spring, and to breed, they require salt; and I know that, if salt is used properly, it will cure foul brood and other diseases."

On page 829, same issue, the editor says: "Friend Coggshall forgets that the salt remedy has been thoroughly discussed at conventions, and carefully tested by scientific men, until it is pretty certain that common salt or salt water has no effect whatever on foul brood."

On page 906, same volume, the editor refers to the alleged salt cure again, and says: "During the whole time that foul brood prevailed in our apiary we used salt in front of the hives, for keeping down weeds. Whenever there was a rain, or even a heavy dew, the bees could be seen in the sawdust around the entrances, helping themselves to their hearts' content. Prof. Cook, or some one else, has reported testing the matter with scientific exactness, and the salt water had no effect whatever on the foul brood."

Now, it seems to me that the better way, in order to discuss the salt remedy intelligently, would be to request friend Coggshall to write out his experience with salt, as indicated, and then publish the same in Gleanings. It seems to me that a bee-keeper who has 600 colonies of bees, and who says that he *knows* salt will cure foul brood, when used properly, ought to know what he is talking about. When he gives his experience in print we may then find that friend C. does not use salt for the cure of foul brood by sprinkling it over "weeds" and "sawdust," but that he has some special way of using it, for he says it must be used properly.

The writer of this is by no means a novice in the management of apiaries afflicted with foul brood. My experience with foul brood began some 30 years ago in western New York, and has continued at intervals from that time to the present. My experience has taught me that a foul-brood apiary can be made about as profitable as a healthy one, and that the disease can also be exterminated therefrom when so desired. But there may be a better way than mine, or any that has been made public, to rid an apiary of foul brood; and this is why I desire to know the details of friend Coggshall's plan, and to have the same published in Gleanings. M. M. Baldridge.

St. Charles, Ill., Jan. 10.

[Mr. Coggshall is a prominent and successful bee-keeper, and we hereby solicit him to reply.]

WAX-MELTING.

WHY FOUNDATION IS MILKY IN COLOR.

There are some who think steam makes foundation milky, and some that heating hot injures wax. Now, steam, if not used right, will make poor foundation, and heating hot will spoil wax; but wax heated in water can not be heated too hot, and steam used rightly increases its value. When melting wax, if steam is used direct, be sure to let all boil together (water and wax) *furiously* for 15 minutes. Then let it stand five hours, and the wax will be perfectly clear—so clear that you can see to the bottom of a dipperful. There is now no water with the wax. If the wax is dipped immediately over into the dipping-can after melting, or if the wax is not heated hot, but only enough to *just* melt it, the wax will be milky, and foundation made from it will look as though full of sand. At our State fair there was 150 lbs. which we clarified for a bee-keeper, and it took the first premium. It certainly would not if it had been sandy. Every one that has rendered wax is acquainted with the refuse on the bottom of the cakes. Some of it is loose, and is easily scraped off. This is in the same condition that the whole cake would have been if it had been heated only just enough to melt, and given a good stirring. If you ever have a cake of wax in this condition, to remedy it put the cake in some water and heat to the boiling-point and boil hard for 15 minutes, then set off the stove, disturbing it as little as possible; cover up so as to keep in a melted state as long as you can. Let it stand for 24 hours, when you can take off a cake of wax just as good as it ever was. Save all the scrapings from the bottom of your cakes, and try this. You will get enough wax from them every year to more than pay for Gleanings.

I wonder whether those who say steam injures wax have melted much that way. We rendered about 1000 lbs. of wax from old combs this last year, and challenge any one to show as nice a lot. It was rendered by steam at a pressure of 80 lbs., blowing directly into the water containing the combs. I don't know of any way to take wax that comes to us, that was rendered in iron utensils, and make it yellow, unless it is the one of thoroughly boiling it in acidulated water. The acid combines with the iron, and sinks to the bottom with the water, leaving the wax free from it, which made it dark in color.

One thing I should like to correct. The acid does not carbonize or burn the organic matter, but combines with the iron, etc., that is in the wax, also with the water, making it easier for the water to soak into the impurities. The hotter the water and wax, the more easily the refuse will settle. In rendering old combs, if we could use something in the place of water that would soak up the cocoons so as to make them heavier than wax, the process of getting the wax from the combs would be very simple.

I have used water and acid, half and half by measure, on old combs, and have succeeded in getting *all* the refuse cocoons and every thing else to settle; but on heating to get the wax to rise, the refuse would come to the top, caused by the steam from the boiler condensing and mingling with what water was there before, and making the refuse lighter. I now have another idea in my head to try. It is, to *wash* out the wax while all is boiling hot. I believe I have something that will work, and something that every bee-keeper can use.

F. A. SALISBURY.

Syracuse, N. Y., Jan. 6, 1892.

So far as our experience goes you are correct, although you are the first one to discover the plan to us. We may add, incidentally, that any foundation, after having been rolled, that is milky, instead of yellow and transparent, may be brought to the latter condition by exposure to the rays of the sun before a window for a few minutes, or by exposure to artificial heat. Any foundation that is used for exhibition purposes can thus be very much improved where otherwise it might pass for a second grade.

COLORADO.

MR. JESSUP EXPLAINS UNCLE AMOS' JOKE.

It is now the 11th of January, and in this time the bees have had four days in which they could enjoy a cleansing flight since Jan. 1, and you may rest assured they enjoyed themselves.

Well, friends, since Uncle Amos has started the joke a going I might as well acknowledge it, and say that it is my treat; but since I neither smoke nor drink, and don't think that any of the rest of the bee-keepers do, I suppose I shall have to set up the candy. To make a long story short, I will tell you how it was I came to ask the senior editor to subscribe for his own journal. We are all liable to make mistakes, and of course I knew he was expected there; but I was so sure that he was another man that I *did* show him GLEANINGS, and asked him to subscribe; for, as Uncle A. I. says, I was very deeply engaged in soliciting subscriptions for it, and I wanted that man to *subscribe* for it. However, it is only a joke, and I am one who can take a joke in as good play as any one, when it is a truthful one.

THE FRATERNAL FEELING BETWEEN BEE-EDITORS.

And right here, while I think about it, is something that I would speak about: It is the general good nature displayed by our brother bee-keepers. Take for, instance, the case of W. Z. Hutchinson and Ernest, as described by W. Z. himself when they were at Albany together, and note the perfect good will and brotherly kindness shown in their travels, and also notice the description of the discussion, too, how their discussion grew "redhot," and still they kept "sweet;" and you might ask why they did. Because it is hard to find a man who has passed the experimental stage (so to speak) of bee-keeping, but has learned the great lesson of obedience and endurance to such an extent that he can at all times control his temper. They have sweetened them with honey, perhaps.

Well, friends, in conclusion I want to say that my dreams of years are fast being realized. I have at last secured me a farm, and am preparing to settle down and make me a home; and I wish to say to my friends and brother bee-keepers in the East, that, when you are visiting in the West just come around and I will endeavor to make your visit as pleasant as it is possible to do. I am located just six miles east of Greeley, on the south side of the Platte River, and my apiary shall be known as the Aurora Farm Apiary. I hope to be able to give you a photo of my home and apiary some time during the coming autumn.

THEO. V. JESSUP.

Greeley, Colo.

THE MAN OR THE HIVE WHICH?

DOOLITTLE GIVES SOME OF THE REQUIREMENTS OF SUCCESSFUL BEE KEEPING.

From the many questions from different correspondents which I receive nearly every day, and from the many who are seeking after the best hive, a hive which will "give big results" every time, it would seem that all one has to do is to procure a Root Dovetailed, a Heddon divisible, Hoffman, Langstroth, Gallup, or some other good hive, to meet with *certain success* in apiculture. No matter how little thought is given to the field, location, or securing the bees in time for the harvest, or how poorly attended to, if we have only a good hive we certainly shall have honey. From the many failures in the bee-business, and the shipwreck ending in disaster of so many who started out joyously when embarking in the business, it would seem as if they depended simply on using, or having in their bee-yard, good hives. While a good hive has very much to do with the results of bee-keeping, the *man* has *much more* to do with success or failure, so far as dollars and cents are concerned. Does a man buy a choice lot of poultry, put them in a nice, well-finished building and inclosure for the same, and let them take care of themselves, expecting a large profit from them? No; the man spares no pains to have them properly cared for, and gives them every chance in his power which will tend toward success. Yet this very same individual, or many very similar to him, will expect a large income from the same number of colonies of bees if they only have them in good hives, no matter whether they do any thing for them once in six months or not. The idea that "bees work for nothing and board themselves" must be banished from our thoughts before we secure much profit from them, and yet this very idea seems to take possession of very many when they embark in the bee-business. *Work*, for a man with brains enough to know that he must leave no stone unturned that tends toward success, is what successful bee-keeping means. A good hive in the hands of such a man is a power which can be used to roll up tons of honey, and show to the masses of the people that there is money in the bee-business. Such a man will have his bees in readiness for the honey harvest whether that harvest comes from white clover, basswood, or fall flowers, and he will do things in just the right time to secure the best results.

I am often asked, "What advantage has a movable-frame hive over a box hive?" *Much*, every way, in the hands of the skillful apiarist, but none at all with the man who does not take advantage of its principles or of the benefits derived by a judicious use of the same, such as knowing in the spring that each colony has sufficient stores to last till flowers bloom, or in the fall that it has plenty of stores for winter, or that each colony has a good prolific queen, or giving stores to the needy by taking them from those having an abundance, etc. What are the movable frames good for if not for the above purpose? and yet we have those all over the land who do not take a frame out of a hive once in a year, yet call themselves bee-keepers, and wonder why they do not succeed in securing some profit from their bees as do some of their more successful neighbors. They have the same hives, they are sure. They are like some persons I know of, who, when asked how the bees prosper, say, "Pretty well, I guess; the hives were all heavy when I set them out of the cellar, and I guess they are yet. Here is a good one. I have lifted it several times, and it is always heavy. That one will give me lots of honey this year." We step to the entrance, and there is scarcely a bee flying, while from others, near by, the working force shows three times their numbers. Upon asking about one of these the owner lifts the hive, and, when finding it much lighter than the other, says, "That is lighter, and I do not think it is as good as the other." We next ask if each has a good queen and plenty of brood, as it is now near the tenth of May, and are met with the reply, "I can't tell; I have not had the frames out of the hive since the bees were put in it. I do not believe in fussing with my bees as some do."

Thus we find plenty of bee-keepers, or those calling themselves such, all over the land. Is it any wonder that we have plenty of candidates for blasted hopes? These men do not seem to realize that it is just this "fussing," as they call it, which makes the success of the prosperous ones about them. I do not want to be understood that a person is to be continually overhauling his hives (as most of the readers of GLEANINGS are aware, from what I have written during the immediate past), that such a person may be successful. No, not that. What I mean is, that, when a gain is to be made by looking inside of a hive, *do it*, and do it at *just the time it is needed*. Tend to the bees in the spring in just the right time; put on the sections in the right time; see that all colonies have good prolific queens at the time they are needed, and so on with all the work of the apiary. Do not keep any more colonies of bees than you can care for and have every thing done in good order. Better results can be secured from twenty-five colonies properly attended to than with one hundred colonies left to care for themselves. What I wish to impress on the mind of every reader of this article is this: That a thorough, practical apiarist will succeed with almost any of the frame hives now in use, while a careless, "go as you please" man, will not pay his way with the best hive ever invented; and it is for the reader of this to know to which of these classes he or she belongs. If to the latter class, *reform* should be the motto to be pasted in your hat.

G. M. DOOLITTLE.

Borodino, N. Y., Jan. 14.

[As usual we quite agree with you in every statement you make. With almost any hive, given a good season, a good bee-keeper, and a good locality, a honey crop and a reasonable amount of profit is sure. Yes, even a box hive, under these conditions, could be made to yield excellent results, for its conditions are, to a certain extent, under the control of the apiarist. M. Quinby made money with it. But while we look at this side we must not overlook the *convenience* of the modern appliances.]

ABSORBENTS IN WINTER.

SOME EXPERIENCE THAT PROVES THEM DETRIMENTAL.

Friend Root:—In your review of the book, "Winter Problem in Bee-keeping," you ask, toward the close, to have the subject thoroughly discussed. Well, while the author, Mr. Pierce, is opposed to absorbents next to the bees, and yourself and your apiarist, Mr. Spafford, seem to coincide with him, I can not, even "for the sake of argument," take the opposite side, but must follow right along in the same line with the author whom you quote, leaving others, whose experience may justify it, to take the other side.

When I first commenced keeping bees, some eight years ago, most of the books I had read, as well as the journals devoted to bee culture, favored absorbents in the form of chaff, leaves, or sawdust, either in cushions or loose, next to the bees, with a cloth of some kind intervening. Accordingly, having no opinion of my own at the time, I thus prepared sixteen colonies for outdoor wintering, using chaff for an absorbent. The bees were in eight and ten frame L. hives, which were mostly contracted to form four to six frames each; these were placed in the center of the hive; and over them, reaching to the bottom-board on each side, was placed a piece of burlap; the spaces left on the sides were then filled with chaff, and on top of the frames was placed a chaff cushion about three inches thick. The hives were then grouped in a row on the south side of a fence, leaving a foot space between hives and fence, and about fifteen inches between the hives. Straw was then piled over and around the hives on three sides—the front end being left exposed and topped out with timothy hay. The straw extended over the fronts of the hives sufficiently to keep them perfectly dry; and in severe weather, planks a foot wide were placed in front to keep the wind from blowing in at the entrances. Snow was not allowed to accumulate in front of hives, and in fine weather the planks were turned down to afford the bees an unobstructed passageway.

Thus cared for, I was confident they would winter perfectly; but what was my surprise, when I unpacked them in the spring, to find eight colonies dead, and the survivors weak, and afflicted with diarrhea! The whole interior of the hives occupied by the dead colonies was damp and moldy, reaching well into the packing, which, in places, was actually wet. When the bees flew in winter the fecal discharges were yellow and unnatural, showing that diarrhea was prevalent among them, and they no doubt died from the effects of this disease, which, I am confident, was brought on by excessive dampness within the hives.

At the time, I thought that too much packing over the hives was the cause of all the trouble. I now think it had little to do with it; for, following on the former conclusion, two years ago I again packed 148 colonies on the summer stands; 120 were in double-walled hives, packed with chaff, a chaff-packed rim placed over the frames, with the chaff piled on till it was six to eight inches deep over the frames. Some of the ten-frame hives were contracted to six and seven frames each, while some of the strongest were left the whole ten frames. The hives faced south, and those contracted had their frames shoved to the east side of the hive; a piece of burlap was put over the frames, reaching to the bottom-board, and the space on the west side filled with chaff. A ten-inch super was placed on each hive, and filled nearly to the lid with chaff.

Now, although the winter was exceedingly mild, bees flying almost every day during December and January, and exceptionally dry, there being no rain of any consequence, the hives were all somewhat damp inside—those with the least chaff over the frames being the dryest. The ten-frame hives, with nearly ten inches of chaff over the frames, were no better off than those in the double-walled hives, while the chaff next the frames was damper—in fact, the burlaps, which were sound and good when put on in the fall, were so rotten that, in most cases, they pulled to pieces when taken from the frames. Still, the colonies were generally strong, excepting three that were attacked with paralysis, blind-staggers, or whatever you choose to call it, and left to go it alone, "petered out."

I am now firmly convinced that absorbents next the bees are a detriment, for the reason that they take up and *retain* the moisture that, from the adverse action of the heat and cold, will accumulate on the inside of hives wintered outdoors in this latitude. I believe they also absorb, and hold for a time, the nitrogenous gases emanating from the cluster; and when they became saturated they precipitate both moisture and poison upon the occupants of the hive. I believe hives should be packed, but that a pine board, and not a chaff cushion, should go next to the bees. W. J. CULLINAN.

Quincy, Ill., Jan., 1892.

[Your experiments only negatively confirm the sealed-cover non-absorbent idea. If you had tried, alongside of those colonies packed with chaff absorbents, others also packed in chaff, but with a sealed cover over them, the experiment might have been more conclusive.]

CONTRACTION.

ITS THEORY, OBJECT, AND RESULTS.

Some years ago, at a convention in Chicago, I was sitting talking with E. J. Oatman before the opening of the session. I told him I would give a good deal to know of some way to prevent swarming when working for comb honey. A little to my surprise he replied, "I would rather have every colony cast a prime swarm." Then putting his hand to one side of his mouth, and speaking in a very low tone, he said, "The secret of it is to hive each swarm on four frames, and let them store for all they're worth, and then double up in the fall." That was the first I had heard of contraction.

Contractionists have been a good deal misunderstood. Some of the theory is easily understood. Suppose a queen is capable of keeping seven frames full of brood. It seems very easy to understand that, if the colony of that queen be kept in a hive of six frames all the year round, when the harvest comes, if the queen keeps the whole six frames filled with brood, the bees can have no help for it but to put all their surplus in the supers for want of any other place. Without taking time to give reasons, let it suffice to say that, in actual practice, a six-frame hive all the year round is a failure, and no genuine contractionist stops his theory in that bound. Yet that is about all the idea a great many seem to have of contraction, that it simply means to keep the room for brood-rearing restricted.

As Doolittle has so vehemently urged, the most important part of contraction is expansion. Use all means to have as strong a force as possible at the beginning of the harvest, and no six-frame hive will do for that. *Then*, when the harvest commences, limit the room in the brood-chamber, and that is the contraction of contractionists.

Contraction or no contraction, few will question the wisdom of getting the strong force ready for the harvest. Beyond this there is room for difference of opinion. Crowding the queen awakens the swarming impulse, unless, indeed, there can be awakened such a greed for storing that queen and all hands may turn their attention in that direction. Is there not naturally a tendency that way in any heavy harvest? Still, there can be no question that unlimited laying room tends to discourage swarming, and hardly more question that a colony that never has the *desire* to swarm is the better for storing, other things being equal. So, on the whole, it is probably right to set down the tendency to swarm as a pretty serious objection against contraction.

"Contraction stops raising a horde that will be too late to be of service in the harvest, and will help consume that harvest after it is gathered." I confess I have been gradually losing faith in that till I have come to the point that I do not believe it at all. Mind, I don't say that I *know* there is nothing in it, only I don't believe there is. The argument is something like this: Suppose the harvest stops July 15. It is clear that all eggs laid in the 21 days next preceding July 15 will raise bees that can not touch that harvest; and as workers do not take to the field till 16 days old, we can add that 16 to the 21, making 37, so there's no use in having the queen lay after June 8, which is 37 days before July 15. But, is it true that bees do not become field-workers till 16 days old? Although that may be what ordinarily happens, is it not governed by the needs of the case? I have seen bees five days old carrying in pollen, and I suspect that those same bees might have been kept from field work till they were much more than 16 days old. Even if they do not go to the fields for 16 days, they can do housework during that time and allow just that many other bees to go, that but for them would be obliged to stay at home. But, theoretically, there ought to be a gain on that harvest, to stop the queen laying to her full capacity 21 days before the cessation of the flow; for during that 21 days none of the eggs will hatch into bees, and it costs honey to feed the brood and bees to nurse it, which bees might otherwise be at work in the field. You see that the argument that bees may work in the field before 16 days old works in favor of contraction at this point.

But then comes the question: "If the queen is limited at this time, will it not work against the future prosperity of the colony?" When I have practiced caging queens, time and again my assistant has insisted that this colony and that colony had swarmed, when I knew that it was nothing but the rapid depletion taking place without any young bees to replace the older ones that had worked themselves to death. Will not such colonies continue to be weaker?—weaker for winter? weaker for the next spring?

But for all that I have said, contraction may be right, and I don't think theory would have made me give it up. I had the theory all straight, and expected good results from it; but somehow the bees were so stupid they didn't seem to see the advantages I was offering them.

Facts are stubborn things, and I don't understand now why my theories haven't worked better. I don't understand why, last year, I didn't get as much from two colonies united at the beginning of the harvest as I had reason to expect from the same two colonies if they had been kept separate. I know that, in all my attempts at contraction, however varied, I have not done as well as when I allowed each colony to have ten frames all the year round. I may as well say here, by way of parenthesis, that I don't believe I want larger than eight-frame hives, but I can't take time just now to explain. The difference in seasons is so great that it may account for all, but I doubt it.

Then there are those two miserable Frenchmen down at Hamilton, allowing their queens to lay all over creation, and yet getting big crops. True, they work for extracted honey, but they have it stored in supers, and don't disturb the brood-nest. I read also of the big crops harvested in France, in the Layens hive with its 20 or more frames, and nothing like the labor given to the contraction system.

To sum it up, contraction makes more work, and I can't feel sure that it makes more honey. I am an expansionist, and it's only fair to say that all true contractionists are; but when it comes to contracting down to any less space than will allow the queen to lay all she will, then I feel, to say the least, that I am in doubtful company. C. C. Miller.

Marengo, Ill.

EXTRACTING FROM SUPERS WITHOUT REMOVING FRAMES.

J. A. GREEN CONSIDERS THE MATTER POSSIBLE, AND SUGGESTS HOW.

I see that, at the Albany convention, there was some talk, though perhaps only in a joking way, of putting a whole super into the extractor at once, without removing a frame. Somewhere back in Gleanings I mentioned this idea, which at that time had shaped itself in my mind. You do not seem to have thought of the practical way to do it. I consider it entirely possible, and I have considerable faith that it will prove practicable to extract honey in this way. If it should prove so it will lead to an entire revolution in the methods of producing extracted honey.

In the first place, the ordinary method of placing the frames in the extractor would probably have to be given up for the radial method. That is, the combs should be placed at right angles to the usual position, so that the sides of the combs are on lines drawn from center to circumference, like the spokes of a wheel. This plan has been proposed before. I am not sure whether it has been tested in actual practice, but I am certain that it could be made to work. The extractor I have in my mind's eye is a large one, in which eight or more supers could be placed at one time. By steam or other power the whole would then be revolved so rapidly that all the honey would be thrown out at one operation, no reversing or sheets of tin between the combs being necessary. An uncapping-machine could be made to run between the combs. Uncapping-machines have been illustrated in the foreign bee-journals, though I can not say as to whether any one uses them.

My plan, though, does not contemplate having any uncapping to do. I would take the honey from the hives before any of it was capped. This thin unsealed honey could be extracted in the manner I have outlined, without any doubt.

By the use of the bee-escape and plenty of empty combs it would be entirely practicable to extract all the honey in a large apiary every day if necessary, leaving the bees free to do their utmost in the way of gathering nectar. Swarming would be entirely done away with, the amount of labor required reduced to a minimum, and, in short, the business of producing extracted honey reduced to a sound business basis.

"What would you do with that raw unripened nectar?"

Well, "there's the rub." Show me how to change this nectar into good, well-ripened honey in a simple, inexpensive way, and I will produce extracted honey at a profit at half the ordinary prices.

I have said but little about this before, because I wanted to experiment for myself before saying much about it. But experiments, to be conclusive, would cost more time and money than I can at present devote to them, so I will ask others to help me in them. Perhaps Mr. Larrabee can take hold of the matter.

Two methods of disposing of the nectar occur to me. One is, to evaporate it by natural or artificial heat into a salable article of honey. The other is to feed it back to the bees for the production of comb honey. It might be kept without fermentation until the honey-flow was over, and then fed back to selected colonies.

I know that, to many, this will look wild and visionary. To such I can only say, "Wait and see."

CANDY FOR FEEDING.

The experience of Mr. A. N. Draper, on page 16, is a common one with those who attempt to make bee-candy for the first time. If the directions in the A B C book are carefully followed, the beginner should have no trouble in making good candy, though he is apt to get it a little too hard. It is wonderful what an amount of water can be stirred up into dry candy. In making candy I would use a kettle large enough to hold a considerable quantity. Dissolve the sugar in as little water as possible—about four parts of sugar, by weight, to one of water. When you think it is almost done, let it boil very slowly while you are testing it. Do this by putting a little into a saucer and stirring it vigorously until cold. Just as soon as you can get it to become hard by stirring it is done, and should not be allowed to boil any more, though it may be set on the back of the stove to keep warm. Take a convenient quantity of this, and stir it until it is just beginning to harden, then pour it into your dishes or other receptacles. You will find that you can make dry solid candy of what would have been only syrup if allowed to cool without stirring. If you want a candy that will not readily dry out, boil it a little longer and add a little honey after removing it from the fire.

It is some time since I made any candy, and I am not sure about the proportions; but I think I have stirred in as much as one-eighth honey, making a nice, soft-grained candy that will keep moist a long time. This makes delicious confectionery. Try it.

The candy made of honey and pulverized sugar is rather the best for feeding; but it is more expensive, as well as more troublesome to make on a large scale.

Friedman Greiner's position on artificial honey is sound. I've got something to say on that point soon.

I am sure, though, he is mistaken about comb honey being damaged when bee-escapes are used; at least, it doesn't work that way with me.

I am surprised to see in the pages of Gleanings such a recipe as that on page 8. And sent by Dr. Miller too! Well, well! What's that yeast for, Dr. M.? And what would be the effect on a man who drank a quart or so after it was "good for use"? J. A. GREEN.

Dayton, Ill., Jan. 6.

[You have hit it exactly; and although some may still be inclined to regard it as a joking matter, a thing beyond possible achievement, we only voice your words, "Wait and see." You will remember that, on pages 683 and 773, Vol. XVI., we experimented quite a little with the extractor on the radial plan—that is, with combs arranged like the spokes of a wheel, how we tried some combs of quite thick honey, said combs having been left in a room near the freezing point. This new scheme of extractor didn't clean the cells as perfectly as one on the ordinary plan; but, oh my! it would extract unripened honey as well as the ordinary extractor. You seem to consider the scheme practicable if you only had some way to ripen the raw nectar. A. W. Osburn, of Cuba; J. F. McIntyre, of California; Thomas Wm. Cowan, of England; L. C. Root, of Connecticut; G. M. Doolittle, of New York, and other bee-keepers of note and large experience, insist that the artificially ripened honey is as good as that ripened by the bees. The two first mentioned, if we are correct, make it a practice to extract the raw honey, and ripen it in large vats. But they have an advantage in locality that many of us do not possess. Now, then, who will have the honor to be the first lucky chap to extract the first ton of honey by this new scheme? If this same chap will then ripen it so that the average consumer can not tell it from the honey just as it comes from the hive, the North American Association ought to give him a medal and a chromo. This may seem like a castle in the air, and perhaps that is all there will be to it; but when there is even a *glimmering* of a possibility of something big, why not investigate?]

JULIUS HOFFMAN'S HOME.

A SKETCH OF IT BY J. H. NELLIS.

Reader, are you discouraged? Has bee-keeping failed to yield the profit you expected? Have your hard work and well-laid plans miscarried? and do you lack the returns you anticipated? Then go with us, in imagination, to the home of a man, who, unaided except by his strong will, untiring energy, and intelligent action, has, in the space of eighteen years, built up two places; who, in this time, has accumulated the paraphernalia to carry on his extensive apiaries; who, at this writing, is thoroughly equipped; has nearly reared a bright, intelligent family; has provided for them the comforts of a pleasant and substantial home, and who to-day, through his ripened and extensive experience, will be able to produce a competence to carry him through his declining years, and give pecuniary aid to his children. This man is none other than Julius Hoffman, whom we had the pleasure to visit and interview a few days ago. Indeed, to an intelligent bee-keeper who, through practice and experience, has a keen appreciation of advanced methods, a visit to Mr. Hoffman's is a feast long to be remembered.

The pleasure of such a visit is greatly increased through the hospitality of Mrs. Hoffman, and by an hour passed in listening to the beautiful and difficult music produced by Mr. Hoffman with his violin, assisted by his daughter Hattie upon organ or piano. To assist the reader, friend Root has produced from a photograph this view of Mr. Hoffman's home.

Unfortunately this is not the best point from which to see the premises, but it was used because it included a number of hives. The reader looks toward the northeast—i. e., the house fronts the south. The bees shown in the engraving are not the home apiary, but a lot brought from out-apiaries, and placed here expressly to show in this picture. The man near the center, in shirt-sleeves, is Mr. Hoffman. To his right stands his daughter Lizzie, a pretty assistant of no mean value. To the extreme right is Mrs. Hoffman, and in the background may be seen other members of the family. At the left appears Mr. Hoffman's faithful man, who has helped for some years.

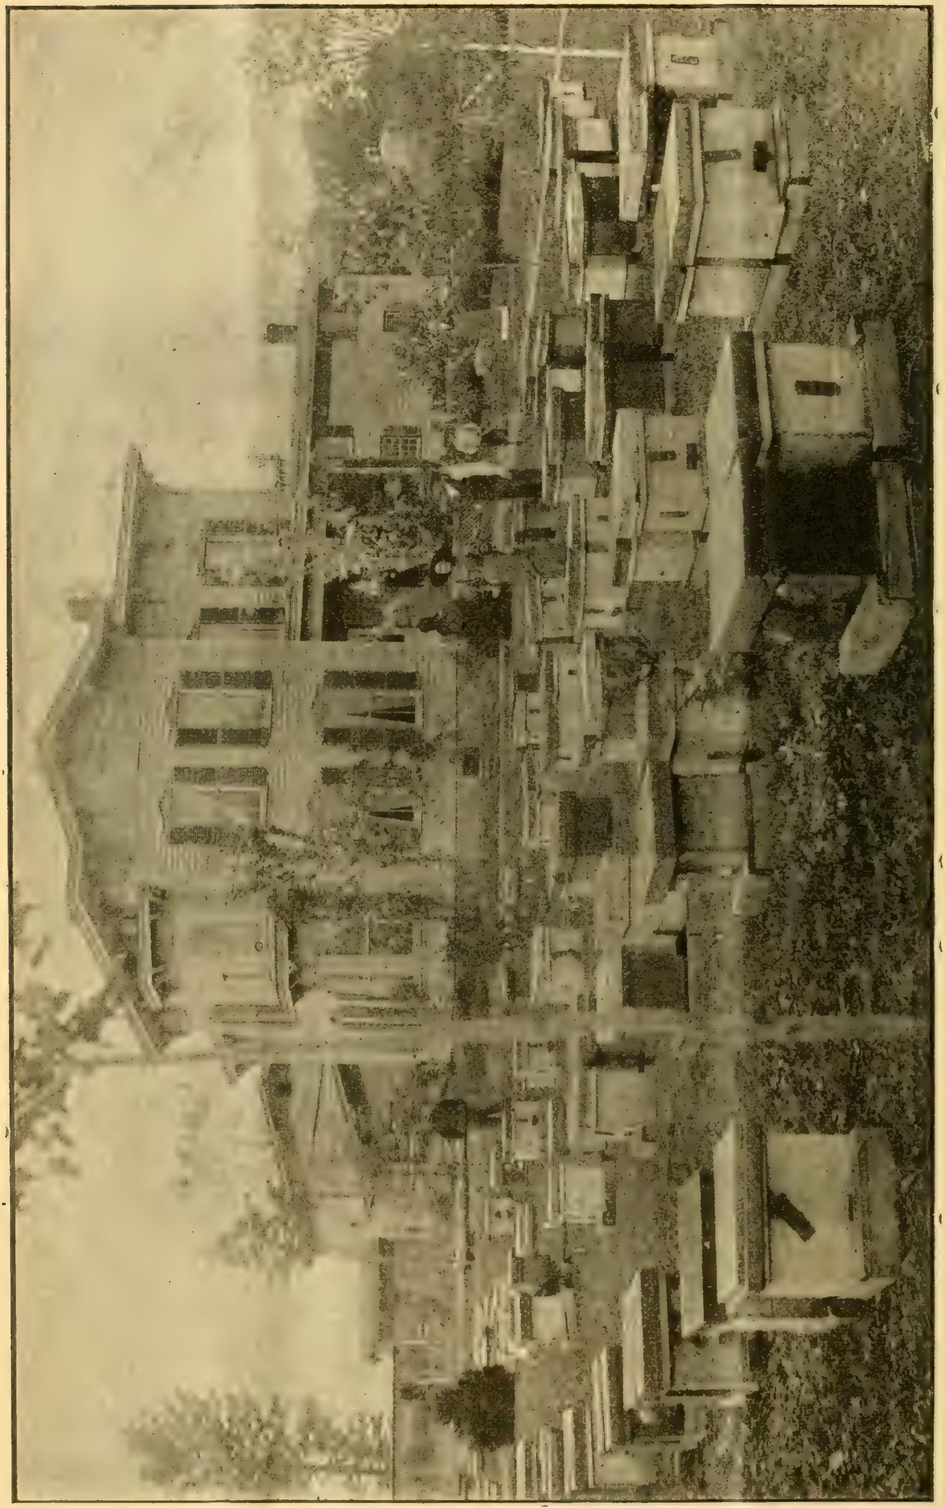
Behind the young man, to the left, can be seen the barn, wagon-house, and farm buildings. To the extreme right, and partially hidden, is the shop and honey-house, a two-story building about 22x32 feet. On the upper floor are stored the box honey, and fixtures used in its production. Underneath is a cellar about 19x29 feet. This cellar is of ordinary construction, about 6 feet 4 inches deep, and has a ground floor, in wet seasons quite damp and muddy. Over a small space, in the vacant end, water stood upon the ground when we visited it.

The temperature of all the cellars is kept as near 45 Fahr. as possible. At this time about 340 colonies are stored in it. The bottom hives are placed upon summer stands (which we will describe later on), and other hives are piled upon these until four tiers deep. The hives are set as close together as possible, and a considerable space at one end of the cellar is occupied by the stairs and a large pile of mangel-wurtzels. Five hundred hives could be placed in this cellar; but this is not advisable, for the temperature gets too high, and good air is not so easily provided. Building-paper covers the floor timbers on the under side, and these are frequently bestudded with huge drops of water. Next season this shop and cellar are to be enlarged to double their present capacity. Under no circumstances would Mr. H. cement or flag the bee-cellars, for he believes that the ground purifies the air and gives off gases beneficial to the bees.

At the middle of January, probably not a peck of bees could be gathered from that cellar-bottom. There is no unnatural hum or indication of uneasiness. To some hives the upper entrance holes were filled with bees to the outer surface.

Mr. H. overhauls and prepares his bees for winter during September and October, and 20 pounds of honey is considered necessary to take a colony through the winter. By lifting the hives he determines the supply. Eight frames are left in each hive, thus providing nearly two inches of space between the followers and ends of hive. Before the hives go into winter quarters, the enamel-cloth sheets used to confine the bees in summer are removed, and several thicknesses of sacking placed over and tucked down into these spaces. Formerly this enamel cloth was left on; but some combs were moldy in spring, which is avoided now. The bees winter equally well whether the enamel cloth is left on or removed. These covers of sacking confine the bees securely and quickly—a great advantage peculiar to the closed ends of the Hoffman top-bars. The hive-caps are not taken into the cellars.

Mr. Hoffman has about 165 colonies under the living-rooms, in his house cellar, and 150 in the cellar of a tenant house, a short distance from his residence. He placed 655 colonies in the three cellars. Two men bring the bees, and Mr. H. places them. The three can put the whole number in the cellars in about ten hours. How they are able to handle this number so quickly



JULIUS HOFFMAN'S HOME, WITH ONE OUT-APIARY TEMPORARILY IN FRONT.

will appear when we describe the hives. During the period from Nov. 15 to Nov. 25, Mr. Hoffman cellars his bees.

If the weather permits—i. e., if no loose snow is upon the ground, and the day is warm, Mr. H. would gladly remove all the bees from a cellar and let them fly during mid-winter. This work can be done for about $1.00 per 100 colonies. When bees remain in cellars four or five months, the mortality arises chiefly from the inability to retain the fæces. If one good fly occurs during mid-winter, Mr. H. is happy, and is then assured that his bees will come out with little or no mortality, and be strong.

Mr. Hoffman assures us that sugar syrup is better than honey for bees in winter; but the sugar syrup is not nearly as good as honey when brood-rearing begins and progresses. Mr. H. is certain that buckwheat honey is superior to white honey for brood-rearing. While sugar syrup is best for wintering, Mr. H. could not be induced to replace the honey with syrup, for the work and expense are too great. He has encountered honey-dew, and finds more difficulty in wintering bees at such times. At the approach of cold weather, honey-dew solidifies, and Mr. H. discovered that, in the damp cellar under the shop, bees wintered much better than in the cellars not so damp. The conclusion: Moisture rendered the honey-dew softer and more acceptable. Mr. H. believes that, when honey-dew is present, or at any time when the cellar is very dry, a supply of water, fed regularly, is worth the cost. He says many of the German bee-keepers supply water during winter and spring. As soon as possible after the bees are set out in spring, the enamel-cloth covers are replaced, for then the moisture should be carefully retained.

Mr. Hoffman scouts the theory that bees void the fæces in a dry state. He never saw any thing to warrant this conclusion, and is satisfied that it never occurs.

Mr. Hoffman has experimented with colonies wintered outdoors packed with chaff and other materials. He has been tolerably successful, but would not practice that system, for it is too expensive in the material used and labor of packing, and in the cost and bulk of the hives and the extra trouble and expense for moving them from place to place.

The home apiary is located some rods behind the shop, so far to the right that the photographer did not include it. In spring this apiary usually contains about 125 colonies, and the out-apiaries, 80 colonies each.

In our next, we will describe the hives and some of their advantages, and explain the methods employed to secure surplus honey and increase.

J. H. NELLIS.

Canajoharie, N. Y.

[Mr. Hoffman is one of those extensive bee-keepers who say but little at conventions, but who nevertheless are wonderfully successful. We presume that there are not a dozen other bee-keepers in the land who have had better or even equal success. His pleasant home and surroundings all bespeak it. He is so modest that we are glad to have him shoved forward. He is an intelligent German, and is therefore thoroughly conversant with the researches and experiments of the bee-keepers of his mother-country; and, besides this, he has thorough familiarity with American bee-literature; and hence, coupled with his large experience, he is able to speak with authority on many subjects. Mr. Nellis has touched upon many things that possibly the reader might like to know more about. If so, please let us know, and we feel sure that he will feel glad to give us the desired information. There is one point which may interest some of the readers; and that is, that Mr. Hoffman has success in wintering in *damp* cellars. Many of us have concluded that dampness is decidedly deleterious in cellar wintering; and yet we have a good many reports of indoor wintering where the cellars were "reeking with dampness." This would be a good topic to discuss, now that our bees are in the cellar, when we can make close observations.]

MELILOTUS ALBA, OR SWEET CLOVER.

HOW IT RESTORES FARM LAND; VALUABLE TESTIMONY FROM THOSE WHO ARE NOT BEE-KEEPERS.

You ask for more testimony from the South on the subject of sweet clover. About a year or more ago I sent an extract from a letter by Prof. Tracy, of our A. and M. College, to GLEANINGS regarding the value of sweet clover as a forage plant, from experiments derived in the cultivation of about 160 acres of it, on the college farm, in which, both for pasture and hay, he gave it high praise; but in that letter he advanced the doubt as to the plant flourishing on other than limestone soils. I now have the pleasure of handing you a communication from General S. D. Lee, president of the same college, to the *Stockman and Farmer*, giving his personal experience with it as a "forage and restorative crop" on one of his private farms.

Editor Southern Stockman and Farmer:—In reply to your recent note as to my experience with melilotus as a forage and restorative crop, I take pleasure in inclosing a letter of Mr. Emmel Dantzler, of Noxubee County, who has charge of my planting interest in that county. He is a gentleman of large experience, and in the six years he has been associated with me has not made a single failure in crops.

He protested vigorously against planting melilotus; but now, after five years' experience, he is a thorough convert, and is gradually substituting it for red clover, both as hay and as a restorer of fertility to worn lands. The backbone of my plantation, which was about worn out, with this crop (melilotus) is now about the most productive land on the place, and is making 1100 pounds of seed cotton to the acre, whereas it made only 600 pounds three years ago, and 30 bushels of corn, whereas it made only 10 bushels three years ago. I consider melilotus 25 per cent better in restoring fertility than red clover. They have been tried side by side for five years. My mules and cattle prefer melilotus as a hay to clover, and it does not slobber my mules. It furnishes two and sometimes three cuttings the first year's planting, and one good cutting the second year, when it goes to seed. The roots are larger than the roots of red clover; and consequently, when they rot the second year, it drains the land better. Melilotus stands drouth better than red clover, and it grows on poor land, whereas it requires pretty good land to insure a catch of red clover. Mr. Dantzler has had from fifty to one hundred acres each of melilotus and red clover for five years. He is now dropping red clover and increasing acres in melilotus, as all the conditions for hay, restoring fertility, drainage, and more certain crop, are on the side of melilotus.

These facts are true on our prairie lands, and are vouched for only for these lime lands. I regard melilotus as the "God-send" for restoring fertility to our worn prairie lands, and in laying the road for changing from cotton to stock in our system of farming. I can not too earnestly urge our prairie-land owners to try it. My plan has been for five years to keep one-third of my place in red clover, melilotus, and lespedeza, and change crops so as to gradually get all my place in grass every four or five years.

The following letter is from Mr. E. E. Dantzler, Cliftonville, Miss., to Gen. Lee. Mr. D. is the manager of Gen. Lee's plantation.

Dear Sir:—Yours, relative to melilotus, at hand. In reply I would state that I have had five years' experience with it. It should be planted in February, but will do as late as the 10th of April. There should be three-fourths bushel of seed sown per acre to secure a thick stand, but half a bushel does very well. The land should be broken up broadcast, and harrowed well before sowing. The plant seeds the second year, then the roots die—but not until it goes to seed. It has but one superior as a hay crop, which is our lespedeza, and it should be cut for hay when it is about fifteen inches high; after that time it is too woody for good hay. I have mowed it three times in one year, but generally twice.

I find it to be a better fertilizer than either peas or red clover. I appreciate red clover very highly, but have abandoned it entirely since I found the advantages melilotus had over it, both as a fertilizer and hay crop. I had a cut of poor land which would not produce more than ten bushels of corn per acre. I sowed it down in melilotus. I then put corn back in it after running it in melilotus two years, and gathered 28 bushels per acre. Cotton land which made 600 pounds of cotton to the acre makes now 1100 pounds after two years in melilotus. I find it stands the drouth and cold better than any other clover. It is adapted to our black and worn-out white lands. I don't think it will prove a success on our red post-oak land, although I have not given it a fair trial. Any information I can give you about this grand plant, write me and I will cheerfully respond. With kind wishes,

E. E. DANTZLER.

These experiments afford excellent proof of the value of melilotus. The experimental stage has been passed, and the fact seems clearly established. The only remaining questions to be solved in regard to the great usefulness of this clover in the near future are: Will it grow advantageously on other than limestone soils? and if so, will it take hold of *impoverished* lands and restore them as rapidly as will cow-peas and other restorative crops?

I am convinced that it will grow and thrive on soil not of limestone formation, here on our average loam on red-clay foundation, but deep and rich. My experience does not extend to poorer or worn-out land. The small patch I have is as luxuriant as any one could desire, growing to 6 or 8 feet high, and so dense that it is a heavy task to go through it—a solid mass of bloom in its season, and swarming with bees from daylight till dark.

Scattered about on the place where seed have been carried in some way are bunches of it, and many of them on poor red clay with little soil on it; and these bunches of it, while not as tall as on the rich spot where I sowed it, grow 3 to 4 feet, and look green and flourishing, besides yearly getting larger, showing they are more than "holding their own." From this, though I have not tried sowing a plat of poor land to it, I have faith to believe if such soil is well prepared, and some cheap fertilizer like ashes or air-slacked lime is sown broadcast over it before or when the seed is sown, it will catch, and that, if it "catches," it will "hold." I shall give it a fair trial before admitting sweet clover is a failure on poor land.

Unfortunately it blooms here with bitterweed, and for this reason it is hard to get at the facts regarding its honey value, quality, quantity per acre, etc. But I feel confident it would equal alfalfa, if grown to the same extent, and that it would supplant bitterweed with the bees, which seem to utilize bitterweed only when sweet nectar to the extent needed is not available, evidence of which we have every fall by securing nice sweet honey as soon as asters and goldenrod come in, though bitterweed is still in bloom.

One more point I desire to notice regarding sweet clover. The piece of ground I have seeded to it is part of an orchard; and though it has the deepest, richest soil on the place, there seemed to be some property lacking, as the trees grew very slowly, being outstripped four to one by those on very much poorer land. Since the dense clover growth, and without cultivation, which they previously had, these trees have shot up like Jack's beanstalk. The clover roots, aided by the dense mulching on the surface, did the business. For two weeks hogs have been allowed the run of this orchard, and I find they greedily eat both stem and root, having torn the place literally topsy-turvy to get at the roots; and the result will be, no clover crop this year, except from the reseeding.

My crop of honey for 1891 was: 2156 lbs. of extracted from 23 colonies; 146 lbs. of section from 2 colonies—2302 lbs. in all, from the 25 colonies. April and May crop was white; June and July crop was dark, but clear, well ripened, and of good flavor and fine body, and sold at 7 to 7½ cents, and gave satisfaction. I have inquiries for it now at 8 cents, which goes to prove that all honey-dew is not low grade, for this later honey was mixed with honey-dew.

My bees went into winter quarters full, both stories. C. P. COFFIN.

Pontotoc, Miss., Jan. 11.

[Many thanks for the facts that you have presented us. Wherever it can be grown, it would be a great boon to bee-keepers, to say nothing of its enriching farm lands. This fact alone will induce farmers to take hold of it. We hope that bee-keepers who are also farmers will try a small patch, and report. The matter is too important to let go by.]

A SUCCESSFUL AUTOMATIC SWARMER.

A NEW YORK MAN SAYS IT IS NOT A FAILURE.

How about automatic hivers? All total failures, you fellows say; or, hold on! there is Dibbern, who says his device, with a leader from the lower hive to one on top, is all right. Tell Mr. D. I published this exact device in the *American Bee Journal* two years ago. I am inclined to believe it would be folly—yes, foolish—for me to explain how to run successfully three or four yards of bees five and seven miles from home, entirely alone, and have entire control of the swarms—yes, or prevent swarms, and take either box or extracted honey.

"Why, Dibble," you say, "you must be crazy."

"Yes, yes; I am. I have been for 15 years, and am actually getting worse all the time. For 15 years I have been putting into practice all of the different devices—bee-hives, section-cases, clap-traps in general. (Isn't this good evidence?) I am aware that your worthy correspondence for GLEANINGS is mighty good evidence on any and all subjects pertaining to bees; but theory isn't practice. Send some of those fellows over to Middleburgh, Schoharie Co., N. Y., next summer, in June, July, or August, and I will show them how to hive swarms in the absence of the bee-keeper; how to prevent swarming, to a certainty, by the proper control of the queen; how to supersede an old queen, or an inferior one, without losing a moment's time in egg-laying.

These three things I believe are bothering the bee-keepers more to-day than any or all the combined things put together. I am crazy enough to say, and invite your especial attendance for proof, or Rambler's, that, with your hive, eight frames and attachments, such as I am using, and in this locality, knowing the honey resources as I do, it is no longer an experiment with me, but facts proven from practice, in my yards, that these three things are easy, sure, and practicable.

I can't make a speech; I can't write much, and I don't expect to succeed in making the bee-keepers think the moon is made of cheese, as some others do; but come and see us, those who are interested in what I am talking about.

Middleburgh, N. Y., Jan. 4. W. DIBBLE.

[You are just the man we want to hear from, friend Dibble; and we hereby invite you to send us a good photograph, accompanied with a description of your automatic swarming-device. Tell us, also, in another article, how you control swarming, and how you supersede an old queen without losing a moment of time—that is, providing you do not intend to keep it a profound secret, as we presume you do not. Perhaps some of our readers will recognize in Mr. Dibble the bee-man whom we called upon in Schoharie Co., while on our bicycle tour. We arrived at his place about noon, just in time for dinner. We had a very pleasant chat with Mr. Dibble, and found him to be an intelligent and progressive bee-keeper. At the time, we urged him to let his light shine more. When we wrote up our travels we presented our readers with a Kodak view of the swarmer, but no doubt Mr. Dibble has perfected it, and would be glad to show it to the bee-keeping public, as it will be impossible for us all to visit him. We suggest the wisdom of our friend not making his invitation too broad, or he will be swamped with callers.]

GRADING HONEY.

HOW W. C. FRAZIER DOES IT.

Since the North American does not seem to have adopted the classification of the Northwestern at Chicago, nor any thing like it; and as a uniform system of grading would, without doubt, be a great benefit to both producer and consignee, there remains nothing to be done except to suggest methods, and hope that there may be, at some time in the near future, a system to which all can agree. I would therefore offer the following, hoping there may be something in it worthy of attention.

COLOR.

Grade "A."

White honey, clover, basswood, and kindred honeys, which are white or light colored.

Grade "B."

Honeys which are yellow or amber, such as alfalfa, Spanish needle, etc.

Grade "C."

All dark honeys, buckwheat, etc.

CONDITION.

"Fancy."

Combs which are well sealed, straight, and even; sufficiently attached to ship without breaking; combs and sections unsoiled.

"Choice."

Combs well filled, firmly attached; not more than one-fourth of the surface can be travel-stained or unsealed, but may be bulged.

"Family."

All honeys whose condition does not warrant placing them in either of the above grades.

Now, in support of the above I have not much argument to offer, as I think it is simple, not nearly as complex as any that have heretofore been offered; also, by it all honey raised in this country could be graded, and its exact quality known. For instance, the best honey from California would be marked "Fancy B." The regions that produce buckwheat honey would mark their best comb honey "Fancy C." while those who are fortunate enough to secure white honey in first-class style could mark their product "Fancy A." The grade marked "Family" will find a much more ready sale, at a better price, than the same honey would bring if marked 3d or 4th grade. It would not take the honey-producers long to learn that "A" means white, "B" yellow or amber, and "C" dark, and then to grade according to condition; and there is no use in having four or five different grades so that it would take an expert to pack honey. The three grades of condition are enough—"Fancy" for the best; "Choice" for good honey, slightly bulged or travel-stained; "Family" for what's left after the two above grades are taken out. Then the letters can be used for grading extracted honey; as it is graded mostly according to color, they would be as applicable to extracted as to comb.

These suggestions I offer. Others may have better systems; but what we want is a simple system that all can understand, and one that will be applicable to all honeys produced from Maine to California. W. C. FRAZIER.

Atlantic, Ia., Jan. 18.

[You have given us quite a scheme; and although it may not be free from fault it will make a good basis from which to work. All the different systems of gradings need to be thoroughly digested—as somebody says, "wrassl'd with," until we may be able to offer something that will be accepted as satisfactory. The fact that there has been so much discussion of it lately shows that there is great need of something of the kind.]

GLUCOSING HONEY.

HOW IT IS SAID TO BE DONE IN PITTSBURG.

Mr. Root: In GLEANINGS you seem to doubt M. H. Tweed's statement about extracted honey being glucosed. There is no doubt that Mr. Tweed's statement is true in regard to packers or firms that make a business of putting up honey in tumblers and other small packages. The —— —— Co., of Pittsburg, have been selling tumblers with something called honey. They have a piece of comb in them, and filled with liquid. They are not labeled honey or any thing else, but simply a strip of paper round the edge of the lid, giving the firm's name. The way their are labeled is a violation of Ohio law, as it does not say what the contents are, nor where put up. In asking the parties that offer it for sale they always say that is pure honey; that the firm putting it up guarantees it to be pure. I have no analysis made of it to prove that it is not honey; but it has not the least bit of honey taste; on the other hand, the taste is disagreeable to me. I have had samples of a great many kinds of honey, but never had any that tasted as this does. It is not the amount that is sold that hurts the trade; but when a customer who knows what good honey is buys some of this it makes him suspicious of honey. I should like to know the proper way to deal with the parties selling such stuff, and how to prove that it is adulterated. If you would like, I shall be glad to send you a sample. H. G. CAMP.

Winona, O., Jan. 23, 1892.

[We have suppressed the name of the firm for the present, and in the meantime will write and find out what they have to say for themselves. We hereby invite all the testimony you can secure. If this testimony is sufficient to convict, and there are laws in Pennsylvania that will cover such cases, we will see what can be done. Now, we are not yet prepared to admit that honey is being adulterated—at least, by the "hundreds of tons," as averred by Mr. Tweed. We should glad to have bee-keepers all over the country give us the facts, where they have good reason to believe that packing-houses are adulterating. We may not be able to accomplish anything; but if we do this much we shall find whether there is even a belief among bee-keepers as to the adulteration of our product. It just occurs to us that, if there is any adulteration at all, it is because the newspapers have been trying to make us believe that it was done on a gigantic scale, and therefore a few of those who are inclined to adulterate would argue that, if they were not in *good* company, they were in a *large* one. There may be a few concerns that would stoop to such low business.

CLOSED-END FRAMES IN AUSTRALIA.

A SUCCESS WHERE PROPOLIS IS THE WORST.

In your issue of Sept. 15, p. 729, appears a letter from J. A. Green, giving his decision to use half-depth frames closed-end. You express great interest in his letter, in your footnote, so perhaps another on the same subject, although somewhat late in appearing, may be of interest to you and others dissatisfied with the loose hanging frame.

As one of the chief objections raised against closed-end frames has been that of propolis, I should like to say, first, that, in this district, there is an abundant supply of it lying around on the ground and under the remains of the grass-tree, or yuccas, and the bees bestow a liberal share on every crack and joint in the hives. It would compete favorably, I feel confident, for tenacity when cold, and stickiness when warm, with that of Cuba, described in your issue of Oct. 1, p. 769, by Mr. T. O. Somerford. I have tested some 100 hives, with closed-end frames 5$\frac{3}{16}$ deep, alongside of some 50 Simplicity loose-frame hives in this apiary for two years. The frames have 1⅜ end-pieces, ⅞x$\frac{5}{16}$ top-bars; ⅞x ¼ bottom-bars, with bee-space back and front of the end-bars, frames hanging, top-bars 19⅛ long. With these frames closed up by two iron thumbscrews and a dummy, I have no more difficulty individually than in moving any individual frame in the Simplicity hive. One turn of the screws gives about ⅛ to $\frac{3}{16}$ side play; the frame near the center is pried apart from its two neighbors with the fingers easily, in warm weather, and lifted vertically up, and replaced as Mr. Green describes, the adjacent frames being close, 1½ inches apart at most. There are no bees caught between end-bars as the frame descends. Contrary to what Mr. Somerford says, these combs can be put into any position in the hives when replaced, and I take no particular care to put them back, except for other reasons that hold good for every kind of hive. I never have to remove the dummy; and while I can handle a *single* frame of either kind, out and in, in about the same time I can handle a *set* of frames of the closed-end type in any matter that involves disarranging and arranging (or spacing) them again quicker and easier than loose frames. Besides this, many operations, as set forth by Mr. Heddon and others, can be performed upon a *whole* colony at considerable gain in time over a similar one upon loose frames. One occurs to me just now with double force, as I painfully learned the difference to-day. Go to one of these hives in the apiary just now — swarming time — and a nice honey-flow till to-day. The queen has possession of three brood-cases of eight frames each (before swarming). With a chisel the lid is loosened, and the cases over the queen-excluder are lifted off; a few jars and shakes, and a light tap of one corner on the ground, and four-fifths of the bees, Cyprian and Italian crosses, are out before robbers (of which yesterday there were none, but a plenty to-day) can well dive in: the cover is on, and the supers are piled up with others near the honey-room, with a Dibbern horizontal escape-board on top of the pile, to drain out the remainder of the bees. Now open a Simplicity two-story hive of twenty frames. Ten times combs have to be lifted and shaken; ten times the bucket has to be opened, and ten times the robbers dive into the sticky bucket and still open hive, kept open for, say, four or five times the period of the former hive.

But this is not all. The real superiority at this time is proved when the empty combs are being replaced later on. If there is the least slack in the honey-flow with us, the first comb put back, sticky and odorous, means bees bent on stinging. By the time ten are put back and spaced properly, the uproar and stings are to be deplored. On the other we lift the cover with one hand; with the other we put on the case of eight combs, all ready spaced, and close up. In less time than it takes to space two loose frames it can be done. And their advantage (I have not seen it mentioned) is, that full sheets of foundation, about 7 feet to the pound, can be safely used, even in our hot climate, in frames only 5 in. deep; nor do I now wire these frames. The frames in the brood-cases and supers are all alike, as described above. As a recent writer pointed out in the *Bee-keepers' Review*, the *full* advantages of handling hives vs. "frame-handling" can not be realized where foul brood is prevalent. As we have ever to be on the alert here for that enemy, there is considerable advantage that our closed-end-frame hives possess lost to us through the necessity of constantly examining combs.

There are only two advantages that I know of in the loose-frame Simplicity hives. They are made up more quickly from the flat, and cheaper, and the frames are turned a little quicker in the extractor than two small frames, though there is less difference here when used to the small frame than might be supposed. The smaller frames are more speedily capped over, and uncapped too, I find, which compensates for the former advantage.

For building up, disposing of brood at swarming time, without increase, and at all times where hive-lifting and comb-carrying, full or empty, is to be done, my testimony is in favor of the shallow cases of closed-end frames, as being less laborious, tedious, and painful, and more economical of time.

It may be thought an additional commendation when I state that, from 90 hives, spring count, I took 11,000 lbs. of honey, mostly extracted, last season, mostly taken in January and February last. T. BOLTON.

Dunkeld, Victoria, Australia, Nov. 18, 1891.

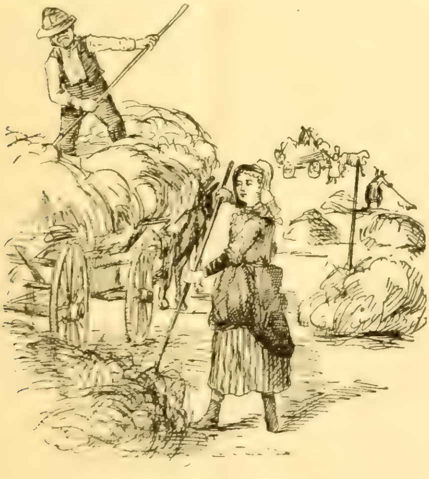
[Propolis is apt to be much worse in warm or semi-tropical countries. It has been stated by some of our correspondents, and no doubt with a good deal of truth, that it is very bad in Cuba—so much of it, in fact, being deposited on the frames and other parts of the hive that fixed distances in the shape of Hoffman or closed-end frames would be out of the question. But several correspondents have stated several times, yourself among the number, that propolis is probably as bad in South Australia as anywhere else on the face of the globe, and yet you say fixed frames are a success notwithstanding. You have stated quite forcibly and clearly why fixed frames are superior to loose frames that require to be spaced. We feel quite sure that bee-keepers who contend that fixed frames can not be handled as rapidly, will find, sooner or later, that they are being left in the race for profit.]

RAMBLE NO. 52.

IN CHICAGO.

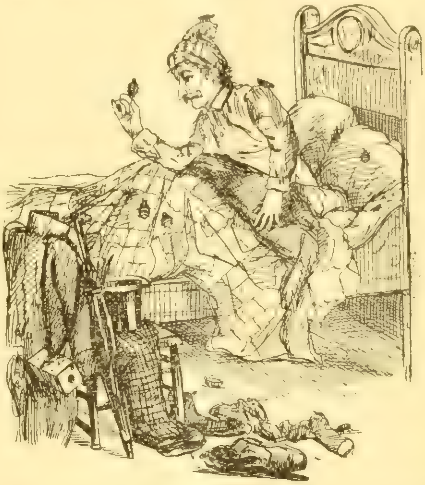
After leaving Dowagiac the route is over a delightful portion of country. On one side we catch glimpses of the sparkling waters of Lake Michigan, and on the other the level and rich farming lands of Northern Indiana. Wheat-fields were quite common through Northern Ohio and in Michigan; but here they became more numerous and larger; the waving fields were ready for the harvester, and many of these machines had commenced their labors. All available help, including women, were at work, and here I first saw women engaged in the stalwart labor of pitching hay upon wagons, and they seemed to use the pitchfork as dextrously as any man. From appearances they were German families who had brought their fatherland love of work, strength, and thrift with them. The average American can not endure to see a woman at work in the fields; the spectacle of petticoats behind a pitchfork or a hoe is not very suggestive of a very gentle, refined lady, which an American loves to honor. The slavery of the kitchen is, however, quite as great, or even a greater barrier to refinement than a judicious amount of outdoor labor, and its attendant pure air and health-giving exercise.

Soon large gardening areas take the place of wheat-fields; the villages become more numerous and larger, and the traveler knows from these unmistakable signs that he is approaching a large city. Soon the houses become continuous; and as we glide smoothly into a large depot, the breakeman shouts out that talismanic word, "Chicago!" How often this wonderful inland city is brought to our attention by some stirring episode within its borders! How often we think of its marvelous growth, and imagine the greatness of its future! And now for two years or more all eyes in the civilized world will be centered on this city, and will place here on exhibition their best efforts of brain and muscle.



GATHERING HAY IN INDIANA.

Chicago is not dejected at all over the herculean-task before her, but extends the hand of hearty welcome to all new arrivals. A whole delegation of her heterogeneous citizens met the Rambler, and every one was vociferous to shake hands. Selecting a broad-shouldered Hibernian to shake with, I was landed unceremoniously into his elegant shay, and rapidly shayed away, with several other distinguished persons, to the Commercial Hotel. This hotel will accommodate 1000 people, more or less. It is run on the American plan so much for a room, and a good price for what you don't eat. The fatigue of the journey sent me early to bed via the elevator. The Chicago night air, the evening cuisine of the hotel, or some anterior circumstance, caused the Rambler to arouse toward morning with a fearful sick headache, and all day the bed was occupied with a despondently sick person. A good rest the second night enabled me the next day to eat a little and make a few short trips on the streets. It is said that first impressions are lasting. As this was a severe stomachic one, it will be remembered. My next impression was through my generous olfactory organ as I approached the Chicago River. A celebrated comedian is said to have remarked, before a Chicago audience, that he heard them talking much about filling in and beautifying along the lake front; but he would advise them to win renown by filling in that immense filthy sewer called the Chicago River. The river, though filthy and loud-smelling, is full of shipping and traffic, and, entering the lake through the business portion of the city, it is spanned by over 60 drawbridges, and undermined by two tunnels. Judging Chicago from the river point of view, the impression is not good.



SOCIALISTIC "CIMEX LECTULARIUS" (BEDBUG).

The Commercial Hotel, charging me for all the meals I missed during my indisposition, I changed to a splendid hotel on the European plan. I was here highly entertained during the night — by several specimens of the genus *Cimex lectularius*, who were evidently in search of rations on the help-yourself, socialistic plan. After this interview I felt decidedly better, and was on the street at an early hour. Wishing to get a general view of the city I ascended the tower of the Auditorium building, and saw on one side Lake Michigan, calm and peaceful; on the other side what I called smoke with a few church-spires struggling through it. A closer observation, however, revealed it to be genuine Chicago gas. Every resident in the city is in duty bound to emit a hundred cubic feet of gas per minute, all about the greatness of Chicago. If this gaseous condition continues to augment, it is predicted, by the oldest inhabitant, that the wonderful tower to be erected will be completely enveloped in this gaseous haze, and be utterly useless as an observatory.

After leaving the Auditorium I went directly up Madison St. to the office of the *American Bee Journal*. Upon entering this famous establishment I found confusion in every department. I didn't know at first but too much Chicago gas here had caused an explosion: but I soon found the true cause. Our friends were having a moving agony, and were going to larger and more commodious quarters. Mr. Newman is a genteel-appearing man of medium height and breadth, and would be readily recognized by any one who has seen his photo in the journals. The son Alfred is a chip from the old block, as far as appearance is concerned: and beneath the exterior I have reason to know there beats a kindly and fraternal heart.

My first acquaintance with the *American Bee Journal* dates back to about the fourth volume, or when edited by its founder, Samuel Wagner, and only a short time previous to his death. The old numbers of those early volumes are carefully preserved. The editorials have a scientific cast, showing that the founder had a love for research, and a power to impart the same spirit to others. The Rambler's first essay in the interests of bee culture will be found in these early volumes, over the name of "Scientific," and not much science about them either. After the death of Mr. Wagner I lost interest in the journal until it was revived by the present editor, since which time I have been quite regularly its patron. The enterprise of the present editor needs no further comment than to refer to the fact that he was the first to give the fraternity a weekly paper. I do not know whether the editor ever becomes discouraged or not; but between the grip and the low price at which the paper is published it would be no more than human if he did.

Let us see—occupying the position it does in the apicultural ranks, and the legal status it has given to bee-keeping through the Bee-keepers' Union, its circulation should be great. It costs the reader less than 2 cents per week. Now, whatever circulation the journal may have, I feel that an addition of ten thousand more would give it such a boom that, though valuable now, it would be enabled to become doubly so. That such a state of things may be accomplished is the wish of the

RAMBLER.

[GLEANINGS desires to second your wish in regard to the old *American Bee Journal*.]

LADIES' CONVERSAZIONE.

CANDY FOR BEES.

WHY A. N. DRAPER HAD BAD LUCK WITH HIS CANDY; HOW TO MAKE CREAM CANDY FOR HOME CONSUMPTION.

After reading Mr. Draper's article on feeding bees candy for winter, Dr. Miller wished me to write something about candy-making, not because I have had any experience in making candy for bees, but because I have had a good deal of experience in making candy for our own consumption, and he thought some of the points might be of use just here. First, Mr. Root, I turned to the A B C to read your instructions for making. You say, "Into a tin saucepan put some granulated sugar, with a little water—a very little water will do." When I make candy I like to know exactly what proportion of sugar and water to use. I think it makes a great difference in results if you know. You also say, "Make it boil, and stir it." Do you mean to stir it when boiling? I can hardly believe you mean that, as I think it will inevitably give you just what you started with—granulated sugar. I have often had it granulate without stirring, and cream of tartar in it besides, while the slightest stirring when boiling is sure to make it granulate. Some sugar is worse about granulating than others.

I suppose your bee-candy is what confectioners call "creamed" candy, which is used in candy-making as the basis of a great many different kinds. If properly creamed it will not granulate, and will keep for a long time. In making, I use 7 lbs. of sugar, 2 teaspoonfuls cream of tartar, and three pints of water, or in that proportion, and never stir in the least when boiling. Let it boil till it reaches the "feathery" stage, as confectioners call it, which is determined by dipping a skimmer in the syrup and blowing hard through it. Whenever you can blow bubbles through the holes in the skimmer, it is done and must be taken from the fire instantly. A great deal depends on taking it off at just the right time.

I now turn the syrup into a large bowl and stir very hard until thoroughly creamed, when it will be milk-white. If too hard it can be made softer by adding a few drops of water, stirring it thoroughly. If too much water is added, the candy will be too soft.

I believe Mr. Draper made three mistakes. First, he had too much sugar for the amount of water used; second, he stirred when boiling; third, he did not cook it enough. He says he set the can with the syrup inside the kettle of water, and water can be heated only to 212°; and although I do not know how hot the syrup must be before it reaches the right point, I feel pretty sure it is considerably hotter than 212°. I think syrup boils at a good deal higher temperature than water. If you have some syrup on the stove boiling, and let it cool down till perfectly still, then drop a little cold water in the syrup, that water immediately boils, showing that the syrup must have been considerably above 212° before it stopped boiling.

It was not only not sufficiently cooked, but, if I understand Mr. Draper, the sugar was not all dissolved, for he says, "163 pounds of sugar will all dissolve; but in order to get it to harden enough to haul to an out-apiary it is necessary to put in from 15 to 20 pounds more sugar," intimating that the sugar was not all dissolved.

You say in your footnote, Mr. Editor, that his candy was too hard. I don't see how it could be too hard. It doesn't seem to me it could be called candy until it had had more cooking. Wasn't it simply water with all the sugar stirred in that it would dissolve, then a little more sugar put in to thicken it? What was there to prevent its being granulated sugar again when the water evaporated? Isn't it the boiling alone that makes all the difference between wet sugar and candy? Even if every thing else had been right, I should imagine that stirring when boiling would alone be sufficient to spoil it.

Since writing the above I have just discovered that you give fuller instructions for candy-making on the next page of the A B C. On page 57 you say, "Make it boil, and stir," which seems to mean to stir while boiling. On page 58 you say, "Take it off the stove at once; and as soon as it begins to harden around the side, give it a good stirring, and keep it up until it gets so thick you can just pour it." In this case you say nothing about stirring until it is taken from the fire and begins to cool. That's good. Stirring while boiling will make granulated sugar. Stirring after taking from the fire, if taken at just the right time, will cream it, which is what I think we want.

Marengo, Ill. EMMA WILSON.

[We believe, Miss Wilson, you have explained why Mr. Draper had such bad luck with his candy. Personally, the junior editor has had no experience in making candy for bees. The article on candy in the A B C book was written by A. I. Root. It is our impression, however, that he desired to have it granulate to a certain extent. When he sees this he will probably explain.]

FIXED FRAMES.

MRS. AXTELL EXPLAINS THEIR QUINBY HIVE; ITS METHOD OF MANIPULATION, ETC.

I have an idea that a large frame works better as a fixed closed-end frame than a small one would, as a large frame gives more space for the bees to gather in the center than a small frame, and so is less liable to kill bees in manipulating them.

Our Quinby hive is just like Elwood's, as shown in cut in GLEANINGS, except that the sides and ends are clamped together at the corners instead of being nailed as his is, and slipped down over the top with the top nailed fast, if I can rightly see it from the cut in GLEANINGS. His hive-body, I see, does not come clear down to the bottom-board either, while ours does, and is held in place by a dowel-pin in each side, that drops into a socket in the bottom-board. Our hive has a flat board on top, tinned over with an inch rim around the sides. When we work through a hive we take off the top and take down the back-board and unclasp one front corner, which lets one side lean over, as the dowel-pin in the bottom holds it up. We can then take out one frame or all the frames, and replace them; then push up the side board that acts as a vise and shoves the frames up tightly. This is the hive we use in the home apiary; but the one we use at the out-apiary holds twelve frames, and a dummy the width of 3 frames, or 16 frames without the dummy or filler. The first hive we bought direct of Quinby, and we made about 100 of them; but finding they were heavy to handle, and as we wished to tier up instead of getting section honey at the sides of the bees we made smaller hives, holding 12 frames. Since then we have put in dummies the width of three frames, and now use only 7 frames to the hive, with the dummy and super holding 36 sections resting on top, as we found we got the nicest comb honey above the bees. In the large hives at the out-apiary we use only 7 or 8 combs with a dummy at one side, and a division-board at the other side, which leaves empty space in the hives during summer; but in winter it makes an excellent outdoor hive for outdoor wintering, by setting the bees in the center and filling in the sides and on top with chaff. We also lift the bees up from the bottom-board about 1½ inches. We used to turn them around in the hive so as to have chaff on all four sides, but that makes more work.

The hives at the home apiary, holding but 7 combs, do not winter outdoors so well as the larger hives. We used to remove the dummy and fill in with chaff, and chaff on top; but for two winters we have not used chaff in the hives put into the cellar, and I think these do better, as the mice worked in them so badly; and warm winters it was difficult to keep them cool enough with from 125 to 150 in one cellar. We raise them up also from the bottom-board. In these large hives we loosen that viselike arrangement and simply shove the frames up tightly together. With care we kill but very few bees. Mr. C. P. Dadant says in GLEANINGS they are "perfect bee-mashers," and he has seen such men as Axtell handle them; but he is mistaken about ever seeing Mr. Axtell handle bees in the Quinby hive, as he has never been at our house, and Mr. Axtell has never been in an apiary with him except in his own apiary, and I believe he does not use the fixed frames.

With care one does not need to kill bees any more with fixed frames than with the loose frame. I should not think so, at least, although I have never handled the loose frames much. With tight end-bars, and boards at the sides of frames, one can make a very warm hive for winter without chaff when set in the cellar, or packed with dry chaff and left out of doors.

We keep our chaff from one year to another rather than gather up fresh chaff each year, as it is more apt to be damp when freshly gathered.

The movable side clamped at the corners is a feature we very much like in some respects. We do not need to remove the supers on top to know the condition of the colony. Simply unclasp one side and take it out; lift out one or more frames and set them back without disturbing the surplus; but unless the frames fit the hives loosely, when first made, or if they fit tight, care must be taken to keep the propolis scraped off from both front and back board, or they will get to fitting so tight it is not so easy to clamp the corners. MRS. L. C. AXTELL.

Roseville, Ills., Nov. 9.

[Your hive differs from the Hetherington-Quinby quite a little. Mr. Hetherington and Elwood do not use the loose sides and top, and the clamping arrangement. When they are not running for surplus, that outside case, or box, sits clear down on to the bottom-board. We believe you said, in one of your former articles, that you did not kill bees, but that your helpers would mash a good many when they put on the end and side boards. This can not occur with the Hetherington-Quinby hive. Mr. Hetherington evidently regarded the original Quinby as too large; and while he preserved the depth of the frame, he shortened it by about two inches. Mr. Elwood uses only six frames on the average. We notice that you reduced the size of your original Quinby, and cut it down to seven frames.]

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

NARROW VS. WIDE BOTTOM-BARS.

Friend Root:—The change you have made in bottom-bars is a good one. I have had a few such frames in use several years, they having come with some bees that I bought. I do not know who made them. I adopted the narrow bottom-bars and made all my thick-top frames with them last year. I have not used many of them in my apiary yet, but my experience leads me to believe that the narrow bottom-bar is better than the ⅞. There is less tendency on the part of the bees to build brace-combs to narrow bars, therefore the frames are more easily and quickly handled. I have not observed any tendency in the bees to draw the comb down closer to the bottom-bar than to the wide—at least, I have not seen any combs connected with the bottom-bar by the bees.

I make the bottom-bar $\frac{1}{4}$x$\frac{5}{16}$, and they go on wide side up. I intend to try them about the same size with the edge up. That will give less surface underneath, and more stiffness to the frames when pulled upward. Bottom-bars might be dispensed with altogether were it not for the fact that they are needed to give strength to the frame; therefore the smaller we can make them, and preserve the requisite strength to the frame, the better it will be.

Wetumpka, Ala., Jan. 20. J. M. Jenkins.

SUCCESSFUL MAILING OF QUEENS TO AUSTRALIA, AGAIN.

The two queens arrived on the 12th of Sept. They were both in splendid condition. The first that I opened had eight dead bees in the box, and the other one had only one dead one. The box with the eight dead ones had consumed the most stores, and the inside of the box was very dirty. The other box was almost as clean as the day it was made. The bees balled one of the queens after they had liberated her, but I saw them in time, for she is laying all right, and does not seem any the worse. She has now got four combs filled with eggs and brood. The other one is a little ahead of her, as she has eggs and brood in five combs. We have every promise of a good season. The bees are beginning to swarm. We have been troubled very much with foul brood, but I am happy to say that mine are free from it now.

James Adamson.

Hastings, Hawkes Bay, New Zealand, Oct. 6.

ANOTHER VICTIM TO GRIP.

Baxter C. Griffith, one of our brightest young apiarists, has gone to join the great majority. His illness was short—only eight days. *Grip* was followed by pneumonia. The only child of aged parents; the father of five lovely girls, and the owner of a large apiary, with no one left to manage it—all go to make his death a peculiarly sad one. His place in church, in state, in apiculture, and in society, will be hard to fill. He was a bee-keeper of only a few years; but by his untiring efforts, and the knowledge gleaned from his many text-books and journals, it is safe to say he was well advanced in the art of bee-keeping. He was a consistent member of the A. R. P. church, and his pastor's loss is hardly second to that of his family. To his bereaved wife we can only tender our sympathy, and point her to Him who does all things well.

Pineville, N. C. A Friend.

MR. DOOLITTLE ON HIBERNATION.

I find but little to controvert in Mr. Doolittle's article on p. 45, except his narrow definition of hibernation. It is *not* turning the word from its legitimate meaning to make it designate the state of quietude, torpor, or semi-torpor, which he describes, and which is necessary to the best wintering of bees, whether out of doors or indoors. Bears hibernate, but they do not "freeze up solid." If a thermometer could be introduced into a bear's internal economy while in a state of hibernation it would register higher than 60 degrees. The bee-cluster is a kind of entity during winter quietude or torpor. Hibernation is not a fixed condition. It has its degrees and variations. See Kirby and Spence's Entomology, and other similar works.

Guelph, Ont., Jan. 23. Wm. F. Clarke.

GLEANINGS FOR JAN. 15, AND THE JUNIOR EDITOR.

Dear Bro. Ernest:—Gleanings for the 15th is here, filled to the covers with good things. Do you know that it is wonderfully gratifying to the bee-keeping world to see that you can so fully fill your father's place as editor of Gleanings? I venture the assertion, that the question has been propounded thousands of times, "I wonder how Gleanings will prosper when A. I. Root is taken away." But He that doeth all things well has provided for the continuance and prosperity of that, of which from its birth he has had a controlling interest. May you *both* be spared yet many years to enjoy its prosperity is my prayer. I want to thank you for the kind words, and prominence you have given me in your very nice report of our convention. I am sorry the meeting was not up to the average, but you have made the reason very plain.

Fremont, Mich., Jan. 19. Geo. E. Hilton.

[Thanks. For the last five years we have had editorial charge of Gleanings so far as it relates to *bees*. If we have done well on the last three or four numbers of Gleanings it only shows that it is not new business to us. We have just been keeping on in the even tenor of our way.]

AN AVERAGE OF 160 LBS. OF HONEY FROM 65 COLONIES, AND AN INCREASE OF 20 COLONIES.

I keep my bees near the Mississippi River, on the west side, and, you might say, in a perfect wilderness of wild flowers on which they work from the latter part of February until about the 1st of November. I commenced in the spring of 1891 with 65 colonies in fair condition, and increased to 85 colonies. I left plenty in hive to do them through the winter, and took, in 1-lb. sections, 2806 lbs.; extracted, 7800 lbs., an average of 160 lbs. of honey per colony. Besides that I saved 122 lbs. of beeswax. I have had to sell lower than heretofore, parties back of Memphis, my best market, underselling me.

R. J. Mathews.

Rosedale, Miss., Jan. 1, 1892.

THE FESTIVE BUMBLE-BEE.

A LITTLE PRACTICAL EXPERIENCE.

When a gentle kind of stirring 'neath a tuft of grass I see,
And I hear the gentle buzzing of a lonely bumble-bee,
Then I know that I shall catch it, and my flesh in fancy itches,
As I feel its little stinger through the seat of my old breeches.
Every tingle of a shingle has an echo as it hits;
But a thousand burning fancies from a bee-sting always flit;
While a thousand bees and hornets 'neath my coat-tail seemed to swarm,
For there's nothing like a bumble-bee to make a fellow warm.
Away out 'cross the meadow I thought the thing had passed,
But soon beneath my coat-tail I knew 'twas sticking fast;
And there it kept a buzzing, and merrily did sing,
And all the time kept playing with its dainty little sting.
There was an intermission, and I thought, "Now, here's my chance;"
And so I struck at Mr. Bee, but only hit my pants.
For that cross bee soon showed me that it could swiftly fly—
It came around so quickly and hit me o'er the eye!
It never stopped a moment, but quickly flew aloft—
My eye, it swelled to blindness—my other end got soft.
Oh loving, tender mercy! cast your pitying glances down,
For I'm the worst used fellow in all this Hawkeye town.
I've had, of fun and sport, all I ever care to see,
And I never more will monkey with a festive bumble-bee.

Muscatine, Iowa. John E. Fultz.

NOTES OF TRAVEL

FROM A. I. ROOT.

LETTER TO HUBER.

Well, my boy, if you were with papa this morning he could show you a lot of funny things. Right in front of the window where I write is a pretty dooryard full of trees, rose-bushes, etc. A path runs down to the gate; and you would expect, outside the gate, a wagon-road, of course. Well, now, there isn't any wagon-road outside the gate at all. Come down with me and see. It is just a great lake of water; and when the tide is high, the water comes almost up to the gate. This water is the "wagon-road" they have off here. Do you want to see the "wagons?" Well, here is one in full sail. It is a very pretty boat, provided both with oars and a sail. "Al" and I went over to the post-office in the boat. Al is Mr. March's oldest boy. He is 18 years old. He put up the sail, and I sat in the stern to steer. It is real fun to steer a boat when the wind just makes it plow through the water. The wild ducks and wild geese were just a gabbling and diving all around us. Al shot some snipes, and they flew out into the water; but the dog that was with us, he just plunged into the salt water and swam out after them, and brought in every last snipe. Al killed 19 at two shots. When we went around the point, Al told me several times to steer pretty well out, as a bar of gravel ran out into the sea. I told him I would be sure and keep out in deep water; but, what do you think? All at once the boat struck bottom and plowed away up into the gravel, and we were "stuck" sure. Al took a pole, however, and finally pushed us out into the water again.

H. A. MARCH'S YACHT.

We went up to the depot and got our freight, and, after it was put into the boat, it made it sink in the water so much that Al couldn't get it up near enough to the shore for me to get in. You see, the bottom of the boat struck the gravel, and I couldn't wade in the water as Al did, because I had been sick. So I went out on the railroad bridge, and Al rowed the boat up against one of the long piles, or timbers, that hold up the bridge, and then you ought to have seen me "shin down" the post into the boat. The log was so big I could hardly reach around it.

There are lots of Indians around here; and as I was very anxious to see them, Mr. March told me Christmas morning there was a tribe of them camping out right near our house. The ground was frozen, and covered with a thin coating of snow and ice; but we found them camping right on the frozen ground. The wind was blowing such a gale I could hardly stand it with my overcoat and all my flannels; but one of the Indian women was sitting on the ground, bareheaded and bare*footed*, nursing her baby with perfect unconcern. The baby turned to look at me, but the wind blew his straight black hair all over his eyes so he could hardly see. Several other women were going about barefooted, often stepping into water with ice in it, with perfect unconcern. Mr. March says they go barefoot all winter long, but never take cold. They have mats made of a kind of cat-tail, that they sit on and sleep on. These mats are also used for shelter, making a kind of wigwam. Oh! I forgot to say the *men* all wear rubber boots, while the women go barefoot. As we started to go away, the old chief motioned to us and pointed to their boat. This was the boat that brought them there, and Mr. March said they wanted us to look at it and see what a nice one it was. I went down, and was very much surprised to find a boat large enough to take quite a tribe of Indians. It was made, or, rather, cut out, of a single log of wood. It was beautifully light and gracefully fashioned, and all done by the Indians themselves. It takes an Indian *two or three years* to make such a boat. This is because they won't use an ax or an adze, but just cut out little bits at a time with a little tool of their own. Lately, however, the younger Indians are learning to use modern carpenter tools. The young Indian girls also wear shoes and stockings; it is mostly the middle-aged or older women who persist in sticking to their old customs.

Well, after I had examined the boat all over, and praised it, the old chief wasn't satisfied. He made motions, took hold of the boat, and grunted, and then we understood that he didn't mean us to *see* the boat, but to take hold and help pull it up on shore where the waves wouldn't wash it off into the water. Friend March commenced to help pull it up; but as I had been sick, I thought I wouldn't lift any; but this didn't suit the old chief. He made motions to *me* to take hold, and then grunted again, to indicate I was to pull and lift too, and to lift *hard*. So I had to take hold, and at least make *believe* that I was pulling a big lot.

The Indians are what they call "Flatheads." They used to fasten a board over every baby's head, so as to flatten down its forehead. You can find pictures of them in some of your geographies. Mr. March can "talk 'Injun'" a good deal, and he sells them apples and all sorts of garden stuff. The Indians live mostly on fish and game. They cure their fish so it looks a good deal like dried codfish. This they put on sticks stuck in the ground close to the fire in front of the door of their tents, and toast it as we toast cheese. I rather wanted some myself; but as I didn't pull on the boat very much, I was rather bashful about asking for a piece. Since I have got well I am hungry about all the time, and I can eat any thing anybody else eats.

Among the other kinds of water-fowl we saw in such abundance on the bay were "Mother Carey's chickens." They are just as cute as can be; but if you just shake your finger at them they dive down out of sight in a most comical way. There are all sorts of divers and ducks that are not good to eat. They say it is because they live altogether on fish. The ducks and geese that are good to cook live on seaweed and other vegetable products. Besides the ducks and geese, there are thousands of seagulls. These are about as large as a common chicken, but have much longer wings. They follow the steamboats in great droves, just to get the leavings of the table after the meals. You see, they just follow the boats until somebody "shakes the table-cloth," and then, "oh my!" what a scampering! They dive right down into the water, like a lot of bees after some honey. They drop into the water, and swim and dive in a wonderful way. They also skim over the surface without moving a wing, until you begin to think they fly without any motion at all. They will skim along by the boat, moving just as fast as the boat does, but scarcely moving otherwise, until it seems like witchcraft. There is a law against shooting them, as they clean up so much rubbish and refuse matter, and so have become very tame. They will sail so close to you that you can almost reach them. I think I have studied out how they fly or sail so long without moving their wings. They collect in a flock, on a certain side of the boat, and keep right there for miles. This place is where the wind strikes the boat and is turned upward. We call it an "ascending current of air." Well, as long as they keep in this it keeps them up. If it blows upward *too* hard, they tip their heads down and sail downward. If not hard *enough*, they will have to flop their wings a little occasionally to keep up. They must be *wonderfully* expert in flying, to keep right in this wind that blows constantly upward, and still keep at just such a height all the time. When the wind was blowing very strong, once in a while a bird would get out of the current I have spoken of, and away he would go like a shot. Why, he would have to fly with all his might for quite a spell to get back to his place with his comrades. I took a lot of them with the Kodak, and hope to show them to you when I get home. They are of all colors, from pure white to ever so many shades, and some of them are beautifully mottled, speckled, and striped, in the most fantastic way. There, Huber, I think this letter is long enough for one time.

Before I take leave of our good friend March and his poultry, celery, cabbage, cauliflower, etc., I want to tell you of a plan of getting two heads of cabbage from one plant. Put out your Jersey Wakefield in the usual way, only use the very best strong plants, and set them on your very richest land; and when the heads are ready to sell, cut out the head, leaving all the outside leaves attached to the stump; that is, cut out the head so as to have no leaves to strip off and throw away, for the leaves are all left on the stump. Now keep cultivating these stumps along with the other cabbages that have not yet headed, and very soon small heads will start out on the stump. Pull off all these little heads but the best one, and this will soon make a head as good as, and may be better than, the first one. I presume this is not new to many of you, unless it is the picking-off of all the little heads except one. Very well; now, these second-crop heads will, many of them, mature so late they may be wintered over in the usual way, and these are the ones friend March gets his choice cabbage seed from. Do you see the point? To keep up the Jersey Wakefield to its best for an early cabbage we want to select seed from the *first* and *best* heads made in the spring; but I never knew how this could be done until now. Simply select the *first good nice head* of early cabbage you get next spring; cut out the head as above, and let it make another, and this last one you can winter over. Set it out in the spring, and you can raise your own seed, and have it from your best and choicest specimen. Or, if you don't want to raise seed, you can have a spring crop and a fall crop from the one cabbage-patch.

THE GREAT NORTHWEST, AND ITS FUTURE.

When friend March sent me his kind invitation, he mentioned the wonderful new town, only three miles from his ranch, a town of 2550 population, which, only *twenty months ago*, was a wilderness. This town is Anacortes. There may have been instances of like rapid growth on record; but if so, I have never heard of it. I expected to find it made up chiefly of buildings of unplaned lumber, put up in the cheapest possible manner. Not so. I was greatly astonished to see fine brick buildings and handsome, stylish residences without number. Their waterworks cost them about $50,000; electric railway of eleven miles, $250,000; ten miles of planked and graded streets, $100,000. An electric-light plant is all completed, and a daily paper has been going for some time, as well as two weekly ones. A school-building to cost $40,000 is nearly finished. A Presbyterian church is completed, and a Methodist church will be ready by spring. I need not tell you of the craze and boom in real estate here during the last two years. Land worth two years ago $20.00 per acre is now valued at, and has been sold for—well, let us say many thousands per acre. Poor men sold half their small farms, where they had lived for years from hand to month, and received in gold more money than they ever expected to see. Then the man who paid them so much gold sold half of *his* half, in less than three days after his purchase, for more than he paid for all. Saloons sprang up until almost every other house, in some parts of the town, was a saloon. But church people were on hand, and churches were started to keep pace with them. The W. C. T. U. has fixed up a very pretty reading-room, right in the business part of the town; and when I went in so many were making use of it that a man rose up and offered me his seat. Sunday evening, I was asked to talk to the Epworth League of the Methodist Church before the regular service at 7 o'clock. I chose for my text, "Ye are the salt of the earth," and applied it to the Christian people, especially to the young Christians of Anacortes. The audience was good and very attentive; and the president of the league, and also the pastor of the church, both indorsed with exceeding kindness the points in my talk. Many of the saloons have already starved out, and, when closely examined, are found to be only a sign and an empty room. At Fidalgo, where friend March gets his mail, they tried to start a saloon. The matter was hotly contested by vote, but the friends of temperance gave up with sad hearts, and much dismal foreboding, when they were beaten by a vote of *one*. The saloon-man was triumphant, paid for a license, and opened up business. Now, what do you think? Why, he never received money enough for his liquors to get back what he paid for his license, let alone profit, and now *his* building, too, is an empty room with a sign over it. When a saloon-keeper is starved out he hasn't energy and ambition enough left to take his sign down. I tell you, friends, there is something hopeful in all this. Public sentiment is advancing. Christianity *is* getting to be "the salt of the earth;" and sometimes we Christians, in our want of faith, don't even suspect how rapidly we *are* gaining ground. Do you wish to know what I think of the future of Anacortes, and a hundred other towns growing in like manner, but perhaps not so fast? Well, I think this: If Christians will remember their divine commission, and push the cause right along with, and side by side of, the boom and real-estate excitement, the outcome will be all right. But, oh let us beware that our "salt" does not "lose its savor," for then shall Satan triumph, and the end will be ruin. The wild speculation in building up a new town can not last long; and, in fact, to make it hold out, people must go to work. If there were more like friend March, who likes to make money by raising eggs, celery, cabbages, and seeds, there would be need of towns and cities; and I was pleased to note how many of his neighbors were succeeding with fruit and other like industries. Puget Sound has wonderful resources in fish, minerals, and agriculture, and both railroads and boats are right at hand to move her produce. I am told that the fishermen of the sound employ 3000 men, and the product is something like a million dollars yearly. Seattle, with a population at present of 43,000, has grown up much in the the same way as Anacortes, but perhaps not so rapidly, and is now a beautiful city, with all the equipments of one of the finest eastern cities. Tacoma, a rival city, about 50 miles distant, has 40,000 inhabitants, and is in many respects a beautiful place. The largest ocean steamers run into all these places, and sail from thence to every part of the world. Even Anacortes boasts that twenty different steamers and steamboats touch her landings every day. O my dear friends! who in this wide world has even a *conception* of the things God has in store for those who are daily seeking, first, the kingdom of God and his righteousness? Y. M. C. A. reading-rooms and buildings are found in most towns of any size; and at Port Townsend the building was lettered on the side fronting the bay, with letters so large they could be plainly read from vessels that passed through the bay; and I saw the same at other towns. This is surely hopeful. Why should not the Lord's cause be plainly advertised as well as the great hotels and saloons? At Anacortes they have a hotel called "Nobar Hotel," and so the sign reads in large letters, meaning that no bar for the sale of liquors is connected with it. And this reminds me that there are more or less vacant hotels in nearly all these new towns. As most of the hotels have a bar, I have been wondering if it is not one reason for it. Building a great hotel when a town is to be started seems to be a sort of mania; and great hotels that have never been occupied at all are seen quite frequently.

Town-building is not always a success; for at many of the railroad stations we find deserted towns, buildings almost all vacant, and boards nailed over the windows. If those who go into such towns would start right into gardening, poultry, bees, and such industries, the future of the town would be assured; for the steamers and railroads take any kind of produce, and pay good prices. In fact, prices are better here for almost every thing than in the East. Great hop-fields are found here and there; and were it not for the hop-aphis this region would probably supply the world. I confess, however, the industry does not make me feel happy. If all the hops raised were to be used for making bread, then might we rejoice; but as by far the greater part of them is for the support of the breweries it is a serious matter. As we come out of Tacoma, toward Portland, on each side of the railroad are some of the finest-looking farming lands I have ever seen. All the underbrush has been cut out, leaving only handsome young firs and cedars. These are in clumps, or scattered here and there through the field. The grass is just like a beautiful lawn, and for miles and miles it looks like a handsome park. This may have been done by real-estate owners or by the railroad company; but even if it has, one can not help admiring their taste.

For fear the boys will neglect the Tobacco Column while I am gone, I think I will put in an item here. Some years ago friend March received a smoker and gave up tobacco, even though he had used it 40 years. It was a hard, bitter struggle, but he came through victorious. As he had a smoker already, he set the new one upon a little shelf, or bracket; and when sorely tempted he would go and look at the smoker, and remember his pledge given through GLEANINGS, and the effect it would probably have should he pay for the smoker, and own up beaten by tobacco. The smoker as an object-lesson helped him to "overcome."

"Mr. Root," said he, as he extended his hand at arm's length before me, "can you hold your hand any stiller than mine is?" I had to confess I could not, for there wasn't even so much as a tremor in one of his fingers; and he resumed, "Well, when I was using tobacco my hand would shake so I could hardly write my name, and I supposed it was because I was growing old; but it was only the poison of tobacco."

Now, dear reader, here is a text and a lesson for you. If you are a tobacco-user, hold out your hand as friend March did. Let your good wife say whether it shakes or not; and if it does, stop before you are a day older.

Now, this isn't all the story of that smoker. After he had conquered, and it did not trouble him more than a year, he still kept that bright smoker in plain sight on that bracket. You see, he had some boys in their teens, and it was well he broke off when he did. Well, one day a sturdy German neighbor came to see him, and to learn about bee-keeping. While he looked on and listened he smoked a meerschaum pipe. His eye caught on the new unused smoker, and he wanted to buy it. Friend M., with a twinkle in his eye, told him *money* could not buy it, but that he would *give* it to him on one condition. Then he told him the story. Our sturdy brother looked at his favorite pipe, and stood aghast at the fearful price he was to pay, and then he doubtless reflected that his nerves, too, were suffering from the nicotine poison. He forgot about the bees, and looked first at his pipe and then at the new smoker on the shelf. For a couple of hours he fought the battle, and considered the matter in all its bearings. Did you ever see a German deliberate on a trade? No doubt he smoked his pipe all the harder, as he made up his mind. But it was finally made up, and he answered, "All right! I take him." He gave friend March his pipe and took down the smoker; and although years have passed, he has never used tobacco since, and, like friend M., is rejoicing in the renewal of youthful nerves.

While in the office of Posson & Son, Portland, who handle bee-supplies for us, a man came into the inner office, where a lady works the typewriter, with a cigar in his mouth. As he went out the senior member of the firm looked at me and remarked that the man had unusual cheek. I asked him if he had read GLEANINGS enough to know where I stood on tobacco. Said he, "Mr. Root, although I have used more tobacco than enough to balance my weight, you can't hate it worse than I do;" and then he told me his experience. Years ago his wife was in poor health; and one day he thought a buggy-ride would do her good. When a little way from home she looked so deathly pale he turned his horse about in alarm, to take her back home. As he turned, the wind blew the smoke of the cigar the other way and she revived. But even then the good and patient wife tried to hide from him the real cause of her sickness. He guessed it, however, and threw away his cigar, and they finished their ride with no more of the faintness. He has never used tobacco since.

Oh! hold on! There is one very important point in friend March's experience I came near omitting. In one corner of the room is a book-rack, filled with choice books, almost from floor to ceiling; in another corner there are as many more. Said our good friend, with a wave of his hands:

"Friend Root, there is my tobacco," and, pointing to the other corner, he said, "there is more of my tobacco. When I gave it up and took a smoker I resolved to use an amount, to buy me a library, equal to the amount I had been using for the purchase of tobacco, and there is the library of *good, useful books*."

Now, it seems to me, dear friends, all this testimony ought to give the Tobacco Column a "boom." It is a *safe* thing to boom, as I suppose you will all agree; and as I sit here and write (in a neat little room in the McLallen House, Roseberg, Oregon) it is New Year's day—the day for starting every thing good. Of course, it will be long past that day when this reaches your eye; but remember that, when the above was written, I prayed that God might bless my feeble words in such a way that *good fruit* may be the result of this testimony of such weight and convincing power. A bright new smoker stands all the while on friend March's mantlepiece. I presume it is to keep fresh in his mind the fierce battle he fought and *won*. Oh! wait a little. I am not quite done yet. When I was at Seattle, Mr. C. M. Sheafe and family entertained me most royally; and while talking over their plans for the education of their three boys (all in their teens, I believe), the subject of tobacco came up. Friend S. broke square off from the habit Nov. 21, so he was right in the midst of the battle at the time of my visit, and I offered him what encouragement I could. I picked up his good wife's little Bible, and read from the third chapter of Revelation, the 5th, 12th, and 21st verses. Dear reader, if you are striving to overcome *any* bad habit, suppose *you* read them.

Friend March gave me the following actual occurrence, which forcibly reminds me of the truth of the little text, "Love ye your enemies; do *good* to them that hate you." Across the bay from Anacortes lived a man noted for his intense hatred of Christians and Christianity. He was terribly profane and blasphemous, and could not find words to express his contempt for ministers, especially for one *particular* minister in Anacortes. One blustering, windy night his house took fire, and burned so fiercely that he and his wife did not save even clothes to protect them from the winter weather. Well, this minister he had abused so much started out before the house was done burning, and raised him money enough to build again; and with the money, and clothing for them to put on at once, he went over in a boat and did his errand as if they had been warm friends all their lives. I hardly need tell you the result. He was humbled to the dust, took back all he had ever said, and has never been heard to swear since then. If any of his old comrades *now* commence to abuse Christians, and denounce the Christian religion, he turns on his heel and leaves the crowd so quickly that his silent protest is perhaps more effective than any words he could use. I think Anacortes may well be proud of such a minister; and, by the way, how many such ministers have you in *your* town? How many laymen? Why, my friend, there is an undeveloped *gold-mine* in these seven little words spoken by our Lord and Master: "Do *good*—to those—that *hate* you."

The junior member of the firm of Posson & Son took me over to see an Italian market-garden. After spending nearly three weeks in Portland and Washington I had made up my mind pretty well what might be done with hardy vegetables in the open air, even during winter time; therefore I was not surprised to find outdoors, without protection, beets, turnips, radishes, lettuce, carrots, peas, spinach, cabbage, cauliflower, onions, and corn salad. Radishes were in all stages of growth, some, in fact, just coming up. Early peas they plant about as we plant corn, only they put from a dozen to twenty peas in a hill. A whole field of them was just coming up, and they looked so much like corn, I climbed the fence and pulled up some. I think such an arrangement would have some advantages for dwarf peas that are not to be brushed or supported. Turnips, beets, and onions are sown at intervals so as to be young and fresh all winter long. The owner said that, once in a while, they had a winter so severe some of the stuff was injured, but so seldom that they take the chances. As the stuff is carried to market every day all winter they are pretty sure to sell a good deal of it any way. Mr. Posson was so determined I should see the famed Will*ah*mette (put your accent on the *second* syllable) Valley, and for other reasons, I swapped my steamer ticket for one by rail. This valley is indeed one of the finest agricultural regions in the world. I saw grapevines as thick as my arm. These were trained on trellises similar to the Fuller system. Even on this New Year's day I saw apples on the ground under the trees in such quantities that the ground was more than covered. I feel sure they were in good condition, but I can't see why the owners should leave them thus when they bring such good prices here. The scenery is beautiful, even at this season of the year, and the bright colors of the many shades of green that adorn the spruces, hemlocks, and various cedars that cover the hills, are hard to describe. The land is pretty much all fenced and under cultivation. Winter wheat seems to be a great staple in the vicinity of Salem; and as the sun strikes it, it adds not a little to the beauty of the landscape. When I suggested to a passenger that this mild moist weather would make the wheat grow too fast for the season, he told me it would; but they pasture it down, and I actually saw sheep turned on the wheat to-day, where the ground is just saturated with rain water. I wonder what Terry would say to such farming. I saw a great many tools out in the fields, and, as a rule, farmers here do not have any such barns or tool-houses as we do east. They say the stock does not need such shelter as we give; and as no shelter is provided, there is no place to put the tools under shelter. I am sure this is very bad policy, for it rains here for weeks together, and every thing is saturated with wet, if it is possible to *get* it saturated.

I was greatly interested in the falls at Oregon City—the more so as there is a little building, clear out in the stream, that utilizes the fall to run dynamos that send electricity *fourteen miles* to the city of Portland. About 20 wires on telegraph-poles carry the current which now lights the city, and they have power to let. These falls on the Willamette River would furnish power and light enough for the whole city, and, very likely, some to spare. It seems to me this is one of the initiatory steps toward a great revolution in power and light, and, probably, *heat* too. River steamboats run up the river as far as Salem, and some, of light draft, as far as Albany. Moss not only covers the rocks and ground, but a species somewhat like the Spanish moss of the South covers almost all the trees. The apple-orchards, when the trees get to be of any size, are so loaded down with it one might almost think they were all killed; but the people say it does not hurt them. In proof of this they point to the great crops of apples that the trees are loaded with. No doubt the moss sets the trees to *bearing*, but it does seem to me it shortens in the tips, and, may be, acts something like pruning. For some reason it seldom if ever attaches itself to the evergreens.

THE OREGON EVERBEARING STRAWBERRY.

I saw this on Mt. Tabor, near Portland, where it is raised by the acre. It is certainly no humbug, as has been intimated, for it has for years given considerable crops of berries, all along in the fall, and sometimes almost up to the holidays. In fact, I saw quite a field of them covered with blossoms and green berries, the latter having been injured by an unusually heavy frost in the early part of December.

"Now, the point is right here," said I to the owner of the grounds; "is it your climate, with its warm weather and abundance of rain, or is it the plant? You have the common varieties of strawberries here in your grounds, have you not?"

"Oh, yes!" replied he; and he pointed to several popular kinds.

"Well, do they produce blossoms and fruit, in the fall, like the Everbearing?"

"I have never seen any; at least, nothing like the Everbearing. Let us look."

We examined a patch of Cumberlands, near by, but not a bloom or green berry was found. He told me the Everbearing did not succeed as it did on his grounds, in some places right in the immediate vicinity. He has for several years sold these berries from August to December, and made a nice thing with them. He sells only the fruit and not the plants.

GLEANINGS IN BEE CULTURE

Illustrated Semi-Monthly
36 Pages 7x10
$1.00 Per Year

In the multitude of counselors there is safety.—PR. 11: 14.

A BOUNTY or no bounty on honey—that's the question.

DR. MILLER says somebody did not report him correctly at Albany. We suppose he means us. Well, doctor, we accept your correction.

THE old *Missouri Bee-keeper*, as per previous announcement, comes out under a new name—*The Progressive Bee-keeper*. The paper is well edited, as usual, and well deserves patronage, not only for the State of Missouri, but for all the States.

WE are glad to renew our regular installment of Stray Straws, and we hope no other unlucky accident will prevent their regular appearance. The straws in this issue are unusually fresh, and sparkling with good nature. The doctor fits the place well.

FOR the last month we have been having quite severe weather. If it should continue thus it might go hard with bees throughout the country. For our locality, however, we are glad of it, as it puts our winter cases to a severe test. Our self-registering thermometer showed that the temperature went down as low as 11½ degrees below zero on the night of the 19th. Since then we have had some cold snaps, but not so low.

CEMENT or grout cellar-bottoms are not recommended in this issue by such good authorities as Dr. C. C. Miller and Julius Hoffman. As many, possibly, may be proposing to put in such bottoms, perhaps they had better wait and investigate a little before going to any great expense for something that might be useless or even worse than useless. We should like to have reports from those who are in position to give us facts in this matter.

IF you discover any lack of editorial sifting in this issue, please lay it to that old fiend La Grippe. It did not get hold of us this time, but it laid low the business manager, J. T. Calvert; and the consequence was, we were obliged to take up his work for a week, and part of the time work nights on GLEANINGS. Mr. Calvert is now back at his post as usual, but little if any worse for his siege of grip, and things are going on as usual again. We presume Bro. Newman, of the *American Bee Journal*, knows how to appreciate the position we were in a few days ago.

IT has been rumored that there is another chap who is about to place on the market artificial honey-comb, filled with glucose, deftly capped over by appropriate machinery. As M. H. Hunt said in his paper at the convention of the Michigan State Bee-keepers' Association, the prospective manufacturers of honey-comb never get any further than they are "going to," or "are about to do so." Bee-keepers need not worry. The newspaper canards have made some fools believe that it could actually be done, and that there was a mint of money in it.

But they are deceived. It never will be done, so that the product can be told from the genuine.

Remember the Ohio State Bee-keepers' convention at Cincinnati, announcements and program of which are given elsewhere. Nothing preventing, we expect to be represented by J. T. Calvert. We have been informed that Dr. C. C. Miller will be there also. His presence insures a good meeting.

The last letter from A. I. Root was to the effect that he was over his nervous chills, and was quite himself again. One day he walked eight miles and another thirteen, climbing the mountains. But our fatherly advice in another column (now on the press) still holds good. We want him to get permanently well and so save himself for many years of usefulness.

The watchword has always been, "Order early;" yet, in spite of this sensible advice, bee-keepers fail to get their supplies in time, even though their dealer is prompt in making shipment. A customer to whom we made a shipment of goods some two months ago, and who has not yet received them, even though we have sent two tracers, wrote us, "What would I do if this were the honey season? or, worse still, in the height, without any goods? I am mighty glad I ordered early, for there will be some chance of my getting them in time yet." Bee-keepers, no matter of whom they order their goods, should remember that freight shipments are sometimes delayed or lost. It sometimes takes a couple of months to recover goods, and sometimes even four.

Some of our customers even yet do not quite understand why we require cash or reference of those with whom we have never had any deal. Perhaps some of these people are bee-keepers whom we have met at conventions, and with whom we have enjoyed pleasant chats. It seems a little hard to refuse them credit; but the strict rules of business require that we know whether such a person is responsible in *money* matters. A man may be affable and pleasant—in fact, a leader in society, and, we are sorry to say, in a few cases, a leader in the church, and yet be very poor pay. If our friends would only understand that, even though they are perfectly responsible, we must have some evidence of it, and that, when we require cash or references, we do not necessarily impeach their honesty, it would save trouble.

One of our subscribers, Mr. F. J. Miller, of London, Ontario, Canada, writes:

> Has not A. E. Manum recovered yet from his honeymoon season? Surely that "queen" is receiving more than usual care, or he would have found time to let us know how he succeeded with those five apiaries alone. No wonder he required help before the season was over.

Mr. Manum promised, some two or three months ago, to write again, and we trust now that he will resume his pen, seeing that the invitation has been renewed. This is not the first inquiry we have had from subscribers, by any means, and we trust that his new queen will spur him up to duty. Yes, we do want to know how he got along with those five apiaries alone. There was a tolerably good honey-flow in Vermont last season, and we are anxious to know all about it.

We take great pride in our short symposium, in this issue, on the subject, "A Bounty on Honey." It is a cause of congratulation to bee-keepers that they have among their number men who are able to discuss these deep and weighty questions in so admirable and candid a way. The discussion on both sides is very fairly and well sustained, and we hold our columns open for its further consideration. Perhaps some of our readers would like to know our own individual opinion. As Gleanings is neither sectarian nor partisan, we think it wise to withhold, at least for the present, our own position. We are sure a little further discussion will, in any event, reveal the right or justice of the thing, one way or the other. There is one thing, however, we ought to say; and that is, bee-keepers should look beyond their own interests enough to consider the general public good. So many selfish and conflicting interests are the bane of our politics.

THE LOCALITY OF GARDEN CITY, KAN., AS A BEE-COUNTRY; A LITTLE ADVICE TO THE BEE-KEEPERS WHO MOVE TO PASTURES NEW.

Two or three months ago one of our correspondents spoke very highly of the region round about Garden City, Kan., as a bee-country, stating that colonies would average 90 lbs. of the very nicest honey, that as high as 180 lbs. had been secured in some cases, and that alfalfa was on the increase. A resident bee-keeper sent in a communication which we published shortly after, protesting that their country was no better than many places in the East; that bee-keepers would be disappointed if they came there with any great expectancy of obtaining great things. Since the appearance of these two articles we have received a number of communications from parties on both sides of the controversy; and as much of it is too personal, and as both sides have had a hearing, we think best to have the discussion stop where it is. Perhaps we ought to say this: That any bee-keeper who would rush into a new bee-country that has been loudly applauded, without making proper investigation, such as writing to a number of resident bee-keepers, would be, we were going to say, a fool; but perhaps "foolish man" would be a more respectable term. Well, there is truth on both sides of the controversy relative to Garden City. As nearly as we can make out, it is something like this: Two knights of old, riding along the road, met under a suspended shield, one side of which was red and the other blue. After a fight in regard to the color, they discovered that they were both right. They had not examined *both sides* of the shield. Although only a little of the Garden City controversy has appeared in our columns, we wish to say to all parties concerned that we believe there is truth on both sides. It makes all the difference on *which side* of the shield we are looking. This same thing happened over A. J. King's graphic coloring of Arizona, as seen on page 628 of last year. No sooner was it published than his bright colors were greatly shaded by a letter from J. W. Johnson, on page 766; and on page 765, same issue, Mr. King has another enthusiastic letter in regard to Arizona, but not so much so as his first one.

MR. AND MRS. A. I. ROOT'S CONTEMPLATED VISIT TO FLORIDA.

Within the past few weeks the whole remnant of Rootville have, in their letters, been urging Mr. and Mrs. Root to prolong their trip in California. The weather has been so very cold here in Ohio, and, as the senior editor's health since he has been away has not been of the best, we made up our minds, now that he was already in the land of flowers and perpetual sunshine, it would be folly for him to rush home again before the California climate and its surroundings could have its legitimate effect in dispersing his chills. It has always been his habit to be on the rush wherever he has been; and now it is of the utmost importance that he take things slowly, and give Nature a good big chance, away from business and its attendant cares. We extend to him a little "fatherly advice" over the printed page, and we presume he will accept it, even if the tables are turned with respect to relationship.

Well, we have also been urging them, as soon as they reach New Orleans by the Southern Pacific, from California, to take the boat and run over to Florida, and make a short sojourn there. This they have partially consented to do. Now, there are doubtless bee-keepers, both at New Orleans and in Florida, who would like to meet them, or, perhaps, would be glad to have them call on them at their homes. If any of our bee-keeping friends in the vicinities named desire to take advantage of this opportunity, write A. I. Root at New Orleans, care of J. W. Winder, 576 Magazine St. Mr. Winder is an old bee-keeping friend of ours, and we take the liberty of having the correspondence reach him via his name. They may not reach New Orleans before the middle of February, and hence you may not get an immediate reply to your letters.

Now, you need not tell him any thing about it, but we have been working a little scheme. They would say it would be impossible for them to go to Cuba; but if we could once get them to Florida, we are then in hopes of coaxing them to go down to the "gem" of the West Indies, and take a look at bee-keeping in its extensive proportions in that favored clime. Mr. and Mrs. Root are not expected to reach home before the first of March; but the weather will still be quite cold at that time, and we hope they may be prevailed on to remain until some time in April. They have been skylarking around the country so fast that we have not been able to follow them nor to give them any fatherly advice as readily as we might have wished. We are sure that GLEANINGS will reach them at the earliest possible moment, for it goes everywhere.

THE ONTARIO BEE-KEEPERS' ASSOCIATION SEVERS ITS CONNECTION WITH THE NORTH AMERICAN.

THE following is a copy of the report of the committee appointed by the Ontario Bee-keepers' Association, to consider the advisability of again affiliating with the N. A. B. K. A.: said report being subsequently adopted in convention:

TO THE PRESIDENT AND MEMBERS OF THE ONTARIO BEE-KEEPERS' ASSOCIATION.

Your committee to whom was referred the relation of Canadian bee-keepers to the North American Bee-keepers' Association beg leave to report:

That the North American Bee-keepers' Association, as its name implies, was originally founded on an international basis, the United States and Canada being parties to and partners in the organization. For upward of twenty years, and until a very recent period, this international character has been maintained, notwithstanding the manifestation of a disposition on the part of some United States bee-keepers to regard and speak of it as a national institution. This feeling took definite and formal shape at the annual meeting held at Keokuk, Iowa, last year, when a proposal to incorporate the association under the State laws of Illinois was made and agreed to.

The delegates from this association, present at that meeting, met the proposal with earnest remonstrance, emphatic protest, and firm opposition; but in spite of their efforts a committee was appointed to incorporate the body, with headquarters at Chicago. One of your delegates was named as a member of that committee; but from what subsequently transpired he was led to believe that those with whom he was associated cared little for his opinion on the subject. Moreover, we have reasons for believing that the official report of the Keokuk meeting, in the matter of the protests made by your representatives there, is largely characterized by a *suppressio veri*; that communications sent by them to two leading bee papers in the United States, discussing the subject, were not published, and that the great mass of bee-keepers within the jurisdiction of the association were denied the information necessary to a full and proper consideration of the matter, and of the means of arriving at a discreet and just decision as to the effect of incorporation if carried out as proposed. A few weeks ago it was announced in the *American Bee Journal* that incorporation had been effected. No particulars were then given. At the annual meeting held a month ago in Albany, N. Y., the report of the Incorporation Committee (which report had never been submitted to your representative on the committee, and who was present at the meeting) was presented and adopted. In brevity and *naiveté* it is an official curiosity. No information is vouchsafed as to the terms and conditions of incorporation. The bald statement is, "The association is incorporated under the State laws of Illinois;" that "the fees are paid, and the certificate in the hands of the secretary." Not a word is said as to its probable effect in the other States of the Union, or here in Canada; but it embraces the important announcement that the incorporators are the "life members *resident in the United States*." The life members resident in *Canada* are quietly ignored. Before the final adoption of this report, one of your representatives at the Albany meeting asked whether "incorporation, as now effected, did not localize the jurisdiction of the association, and make it an Illinois institution," and was answered that the association was "now local, *but its influence would be national*." When he put the question in another form, he was told, "It was necessary to incorporate under a State law, but the organization would be *national* in its character."

Your committee is not in a position to express an opinion on the future influence of the association, or to closely scrutinize its character; nor is it within its province to inquire what particular relationship it bears to the bee-keepers of the United States resident *outside* the limits of Illinois; but it has come to the conclusion that Canada has no rights under the new state of things, and that it was not intended she should. This is amply clear from the fact that her life-members are not among the incorporators, and that the widest character and influence claimed for it, by its promoters, are "national" and not international.

Your committee considers that the changed nature of the association is not a mere innovation, but a complete revolution in the groundwork and nature of the institution as it was heretofore constituted. Before, it was broad and international; now it is local, with but a declared national influence, and your committee look upon this change of organization as a gross violation of an existing compact, deliberately carried into effect in the face of the vigorous protests of your representatives.

Your committee are unanimously of the opinion that the only course open to the bee-keepers of Canada, consistent with independence, self-respect, and national dignity, is to retire from a position which has become, through no fault of theirs, anomalous if not humiliating, and therefore recommend that the Ontario Bee-keepers' Association do not continue in affiliation with the so-called North American Bee-keepers' Association.

Your committee has no hesitation in expressing the belief that the bee-keepers of Canada regret the circumstances that compel the severance of ties which have pleasantly existed for more than a score of years, and in their name tender to the great body of American bee-keepers, which it believes are not responsible, the assurance of our continued fraternal good will, our high consideration and cordial regards, and of our readiness at all times to co-operate with them in any enterprise calculated to further the interests of the industry in which we are alike engaged.

All of which is respectfully submitted.

R. MCKNIGHT.
WM. F. CLARKE.
S. CORNEIL.
ALLEN PRINGLE.

The above came to hand from the secretary, and his language is couched in such a form that one *might* get the impression that in the sending of it he was doing a disagreeable duty, and simply acting under instructions. We were greatly surprised and pained upon reading it—surprised, because we are certain that none of the members who were instrumental in having the N. A. B. K. A. incorporated had the *least thought* that that action would cause the Canadian brethren to withdraw. We were pained, too, because of some statements in the report that are calculated to carry the impression that we desired to put out from the N. A. B. K. A. the Canadians and break down their "national dignity," etc. Nothing could be further from the real truth. We have since received a private letter from one of the members of the committee, to the effect that the grievance was not against the bee-keepers of the U. S. as a body, but against a *few* of the leaders, and mentioned Thomas G. Newman. Dr. A. B. Mason, Dr. C. C. Miller, and the two Roots. We know that every one of the gentlemen named will be as much surprised as ourselves; but they will doubtless speak for themselves.

We greatly regret that the two members who were present at Keokuk should still misunderstand (we can not believe intentionally) the *purpose* of incorporation. Although it has been explained heretofore, it seems they have entirely overlooked the fact that organizations in the United States that are national or international in their character and influence, are, or should be, incorporated under the laws of some *one* particular State; and, as was also ably explained by Capt. J. E. Hetherington, at the Albany convention, incorporation *does not* make the association local, but a legal body politic, amenable to the laws, with special functions, rights, duties, and liabilities; capable of suing and of being sued—in short, transacting business. It is quite probable that the members of the O. B. K. A. as a *body*, not being familiar with the laws of the United States, were not in position to appreciate what incorporation on this side of the line means. We could not incorporate under both the national governments, nor under the laws of the United States, but under the laws of some one State. But, we repeat again, the North American is not less international now than before. Let us give one illustration of what the society now under incorporation is capable of doing:

As a body it can sue any packing-houses in any State, where the laws are strict enough, that may be engaged in the adulteration of honey. It is in better position, also, to protest against injurious legislation from national or State governments, because it is an incorporated body.

Nine-tenths of the bee-keepers of the North American are residents of the United States; and Chicago, the place of incorporation, is the most central of any point for those bee-keepers. The great *mass* of them in the United States are in the North. This our subscription-books show very decidedly. Nothing was more natural than that the State of Illinois should have been selected; and it seems to us, to speak plainly and in all kindness, that nothing but a partisan spirit, or a silly quibble on technicalities on the part of the committee, could make any objection to it. We have no grievance against the *body* of the Canadians who voted for the adoption of the report, for they were acting in good faith. Some of our warmest and best friends we number among the Canadians.

The report goes on to say, "We have reasons for believing that the official report of the Keokuk meeting, in the matter of the protest made by your representatives there, is largely characterized by a *suppressio veri;* that communications sent by them to two leading bee-papers . . . were not published." We have before us the report of the Keokuk convention, as written by the secretary, C. P. Dadant. The report had to be brief, necessarily, on almost every subject that was discussed; and yet it seems, as we look it over, that the Canadian brethren were given a fair hearing. GLEANINGS was one of the leading bee-publications designated, that is *said* to have suppressed one of the communications. The matter at the time was "not available;" and, moreover, we were sure the writer did not properly understand what incorporation meant on this side of the line, and we thought it useless to stir up discord or partisan feeling over misconception and misunderstanding. We were not aware, until we read the report as above, that the life-members in the United States only were the incorporators. We are very sure that the Canadian life-members were left out for no other reason than that the laws of incorporation require that the incorporators be residents of the United States. By the way, if we are correct there is only one life-member in Canada, and twelve in the United States. The Canadian member is D. A. Jones, and we are sure he would never quarrel with us on that point; and of the committee who make this as a big handle, not one is a life-member.

Reference has been made to the fact that bee-keepers on this side have called the North American "national." As we had no really distinct national association, the nearest to it was the North American Bee-keepers' Association; and when "national" was used it was employed as a convenient term, without any thought of excluding Canada.

As an evidence of the fraternal feeling, we presume it will do no harm to let out the secret that there was a strong effort on foot at Albany to put S. Corneil, a Canadian, in as president of the N. A. B. K. A. for the ensuing year. A number of members, including President Elwood, approached the writer on the subject, asking whether he would vote for him, and what he thought of our Canadian brother for the position. We not only indorsed the name, but said we would give our support to it, which we did. Those who were present at the Albany convention know well that Mr. Corneil would have been elected president if he had not absolutely refused to accept the honor. After this we were a little surprised that his name should appear among the members of the committee who drafted the report as above. This ought to show, beyond a question of doubt, that the American bee-keepers, who are members of the North American, desired to recognize Canada, and desired, also, to continue their past pleasant relations, as we had done heretofore. Mark this: The very bee-keepers who voted to elect Mr. Corneil are the *same ones* who voted to adopt the article of incorporation.

Now, brother bee-keepers across the line, does this not show that the idea of crowding Canadians outside of the association was the furthest from our thoughts? and does it not prove that we on our part desired to continue our pleasant fraternal relations?

We have taken a good deal of space to reply to this; but the reason we have done so is because it is an international matter; and now that the O. B. K. A. has taken the action that it has, it is proper that, as one of the Roots, and as a member of the N. A. B. K. A., we should explain our side so that our Canadian brethren can see that we were not intending to break down, nor even thinking of breaking down, their "independence, self-respect, and national dignity." If the Canadians refuse to reconsider, of course that will leave our association distinctly national, for Canada has been the only nation, outside of the United States, which had a voice in the proceedings of the North American.

CIRCULARS RECEIVED.

Catalogues have lately been received from the following:

W. W. Bliss, Duarte, Cal.
S. C. Gorham York, Neb.
Harris & Brown, Lamine, Mo.
E. T. Flanagan, Belleville, Ill.
G. W. Cook, Spring Hill, Kan.
M. H. Hunt, Bell Branch, Mich.
G. K Hubbard, Fort Wayne, Ind.
Mrs. Jennie Atchley, Floyd, Texas.
Gregory Bros & Son, Ottumwa, Ia.
St. Joseph Apiary Co., St Joseph, Mo.
I. J. Stringham, 92 Barclay St., New York.
W. T. Falconer Mfg. Co., Jamestown, N. Y.

We are now printing a fine catalogue for Levering Brothers, Wiota, Ia. We have just finished the annual price lists of E. H. Trumpers, Bankers, Mich., and J. B. LaMontagne, Winter Park, Florida.

We have just printed W. S. Pouder's annual price list of apiarian supplies, 32 pages—175 East Walnut Street, Indianapolis, Ind. Friend Pouder has also just published a primer on api culture, entitled "The Busy Bees, and How to Manage Them." It is sold at the nominal price of 10 cents, and fairly bristles with good points for those who have had a little experience with bees, but who meet difficulties of various kinds. It is worth the price to any bee-keeper.

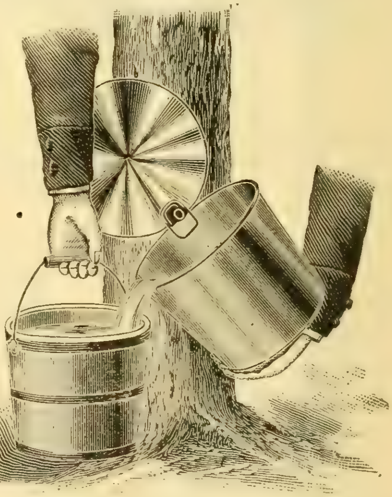
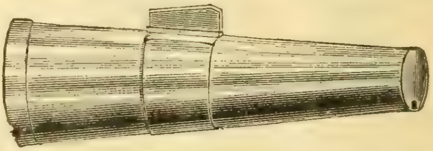
POSITIVELY by return mail I will ship warranted purely mated Italian queens at $1 each; tested, $1.50; select tested, yellow to the tip, $2. I guarantee satisfaction, and refer you to A. I. Root, W. Z. Hutchinson, D. A. Jones, or my thousands of customers.
W. H. LAWS, Lavaca, Seb. Co., Ark.

Sugar-Making Supplies.
Maple-sugar-making time is at hand, and some are inquiring the price of supplies. First, you should supply yourself with that excellent book by Prof. Cook, "Maple Sugar and the Sugar-Bush;" price 35 cents; by mail, 38c. By studying this you may save many times the price of it. Notwithstanding the advance in the cost of tin, we are able to offer you sap-buckets and spiles and cans at last year's prices, as below:



Above cut shows a bucket hung on wire loop, with hinged tin cover, and manner of emptying.



IMPROVED RECORD SAP-SPOUT.
Record sap-spouts, $1.00 per 100; $8.00 per 1000
10-qt. buckets, IC tin, $16.00 per 100; IX tin, $18.00.
12-qt. buckets, IC tin, $17.00 per 100; IX tin, $19.00.
Patent hinged covers, $6.00 per 100. Reversible wood covers, $4.50 per 100. Wire loops for wood pails, 30c per 100; for tin pails, 25c per 100. 1-gal. square cans, 50 or 100 in a crate, $12.00 per 100. Boxed 10 in a box, for re-shipment when filled, $1.50 per box; $14.00 for 10 boxes.
A. I. ROOT, Medina, Ohio.

HONEY COLUMN.

CITY MARKETS.

DETROIT. *Honey*.—No change in price since last quotations. The supply is decreasing, and the market will be bare before the new crop is ready.
Beeswax, 26@27. M. H. HUNT.
Feb. 8. Bell Branch, Mich.

CHICAGO. *Honey*. The demand is not very large, but choice comb is selling at 15@16; other grades are slow at uncertain values. The demand for extracted is fair with prices ranging from 6@7@8.
Beeswax, 27c with demand good.
R. A. BURNETT.
Feb. 8. 161 So. Water St., Chicago, Ill.

CINCINNATI. *Honey*. Demand is good for extracted honey at 7@8 on arrival. Comb honey is in fair demand at 12@16 in a jobbing way, for best white. *Beeswax* in good demand, at 23@25 for good to choice yellow on arrival. CHAS. F. MUTH,
Feb. 8. Cincinnati, Ohio.

KANSAS CITY.—*Honey*.—Demand poor. Supply large of comb, 1-lb. fancy white, 15; dark, 8@9. Extracted, light demand, supply light; white, 7@7½; dark, 5@6. *Beeswax*, none on the market.
HAMBLIN & BEARSS,
Feb. 8. 514 Walnut St., Kansas City, Mo.

SAINT LOUIS. *Honey*.—Market tame; little inquiry. Comb 10 to 12. Extracted, cans, 6½@7. Barrels, 4½@5½. *Beeswax*, prime, 26.
Feb. 8. D. G. TUTT GRO. CO.,
St. Louis, Mo.

SAN FRANCISCO. *Honey*.—Honey remains very firm, as the prospects for next season, at the present time, are poor. We quote: extracted honey, 6@6¾c; and comb honey, 1-lb. 11@13; 2-lb., 8@11. *Beeswax*, scarce, 24@26. SCHACHT, LEMCKE & STEINER,
Jan. 23. San Francisco, Cal.

PORTLAND. *Honey*. The honey-trade has been somewhat dull since the holidays, and prices for comb are not so stiff as they were, although stocks generally are light. Fancy white, 1-lb., sell to-day at 16@17; darker grades, 13@15. Two-pounds, 1c per lb. less all around. White extracted, 8c; light amber, 7c. *Beeswax*, not quotable.
Jan. 11. LEVY, SPIEGL & CO.,
Portland, Or.

KANSAS CITY.—*Honey*.—The market is well supplied with both comb and extracted, selling slow. 1-lb. white comb, 14@15; dark, 8@12; white extracted, 7½; dark, 5@6. *Beeswax*, light supply, good demand at 23@26. CLEMONS, MASON & CO.,
Feb. 8. Kansas City, Mo.

ALBANY.—*Honey*.—The demand for comb honey continues light, and the supply is ample. Extracted in good demand with a small stock on the market. We quote: White-clover, 1-lb., 11@13; mixed, 10@11. Buckwheat, 8@10. Extracted, light, 7@8; dark, 6@7.
Feb. 11. CHAS. MCCULLOCH & CO.,
Albany, N. Y.

NEW YORK. *Honey*. Little demand for comb honey, with sufficient stock. We quote: Comb honey, white, 1-lb., 13@14; off grades, 11; buckwheat, 9. Extracted, basswood and clover, 7@7½; California, 7@7½. Southern, 65@70c gallon. *Beeswax*, scarce and advancing, 28@29.
Feb. 9. HILDRETH BROS. & SEGELKEN,
28 & 30 West Broadway, New York.

FOR SALE.—California 2-lb. section comb honey at 12c per lb. Wis. and Mich. 1-lb. section candied comb honey at 11c per lb. If you want honey of any description, write us. S. T. FISH & CO.,
4-5-6d 189 So. Water St., Chicago, Ill.

WANTED.—An apiarist to tend 190 colonies bees; foundation-mill, 2 extractors, and 200 lbs. comb furnished; also wagon and team. Will give one-half bees (increase) and one-half honey.
3-4d E. Y. TERRAL, Cameron, Texas.

WANTED.—To exchange a *new* 22-cal. Stevens rifle, with globe sights, cost $20.00, for an incubator; must be in No. 1 condition. 4d
J. S. WARNER, Medina, O.

WANTED.—To exchange $35.00 saw-table, Stover's Ideal feed-mill and horse-power combined, and a lot of job type. Want supplies and honey.
2tfdb O. H. HYATT, Shenandoah, Page Co., Ia.

WANTED.—To exchange, red raspberry and blackberry plants for pure Italian queens, or eggs from pure poultry. E. R. MILLER,
4-5d Garden City, Cass Co., Mo.

WANTED.—For 1892, as learners, two young men, brisk, honest, and temperate. Can back instruction by 35 years of active experience in apiary.
4-5-6 S. I. FREEBORN, Richland Centre, Wis.

WANTED.—A man to handle my bees the coming season. FILMORE COLE, Lima, O. 4tfdb

WANTED.—To exchange a fine target gun for foundation.
D. BENNETT, Union Furnace, Ohio.

WANTED.—Situation in an apiary, a single young man of four years' experience. 4-5d
A. C. FUHRMAN, Pleasant Home, O.

WILL exchange Italian queens for Brown Leghorn fowls or eggs. W. C. GATHRIGHT,
4d Toccopola, Miss.

WILL exchange lot 50 x 142 feet, well located, in Larned City, for high-grade bicycle, typewriter, or Barnes foot-power machinery. A. H. DUFF,
4d Larned, Kansas.

WANTED.—To exchange 60 straight brood-combs in L. frames at 12 cents each for supplies in flat. E. D. BARTON, East Hampton, Mid. Co., Ct.

WANTED.—At once, a man to go to Lake Worth, Dade Co., Florida. One who is competent to rear queens and take full management of an apiary. State age, experience, and salary expected per year. HARRY STITES, M. D., 1500 Sixth St., Harrisburg, Pa.

WANTED.—By young man, agreeable outdoor employment during summer, in a pleasant, healthful locality. Have a little knowledge of bee-keeping. Address H. B., Box 151, Bellevue, Pa.

Free. 28-page **RESTRICTOR** book. How to avoid swarms, brace-combs, and losses in winter. How to get bees into sections in one hour; and rear queens in full colonies, etc., same old fixtures. C. W. DAYTON, Clinton, Wis.
24-23db Please mention this paper

EARLY QUEENS,

FROM our branch Apiary in Texas, which is three miles from any other bees, and none but the **best FIVE-BANDED Golden Italian Queens** used to rear Queens and Drones. Our bees are the gentlest, best workers, and most beautiful bees known. Safe arrival and **entire** satisfaction guaranteed. one Warranted Queen, March and April, $1.25; 6 for $6.00. If you want the **best,** send for our circular **at once.** 1-24db

My 654 Colonies of Italians

Are wintering well, and, as usual, I will sell a limited number of them to reduce stock to the required number. Each hive shipped to my customers will contain a full prosperous colony of Italian bees, with a last year's tested queen, on eight Hoffman frames of brood and honey. As my main object in handling bees is honey, we raise all our queens in full colonies from cells built under the swarming impulse, using the choicest and most profitable stock to breed from.

Safe arrival guaranteed in May and first half of June. For terms please address

3-8db **JULIUS HOFFMAN,**
CANAJOHARIE, N. Y.

☞In responding to this advertisement mention GLEANINGS.

Good Queens Cheap.

300 tested Italian queens, raised last season, for sale at $1; $10 per doz. A few hybrids at 25c each. They will be shipped about June 15th to 25th, or later if desired. Have order booked now and send money when you want them. My bees have been *BRED FOR BUSINESS*, and these are bargains. Nuclei and full colonies at very low rates.

Send 25c for sample by mail of

THE UTILITY BEE-ESCAPE.

Thoroughly tested, practical and cheap. It cleans them out and they stay out. Any one can make it. Get a sample and make your own. 4tfdb

THE JANUARY REVIEW

Is now out. It contains articles from W. F. Clarke, and Ernest Root, upon "Writing for the Bee Journals." R. L. Taylor shows how much it costs, or *ought* to cost, to produce comb honey. Mr. S. Corneil explains how, with but little trouble and expense, any one may know if his bee-cellar is too damp. R. C. Aikin furnishes a long, interesting account of "Colorado, its Soil, Climate, and Alfalfa Farming, and how the latter furnishes Honey." The inimitable Hasty begins in this issue what is to be a series of articles entitled: "Comments on a Beginner's Day-Book." This "Day-Book" was kept by Mr. Hasty when he first began bee-keeping. E. T. Flanagan tells how he has bridged over poor seasons. Most of the articles are embellished with a portrait of the author. There are the usual extracts and editorials, including an account of the trip to Albany, and a "leader" upon the special topic for the February issue, viz., "Grading Honey." If you would like to see this number, send ten cents, and with it will be sent the December number; and when the February number is out, that too will be sent. The REVIEW is $1 00 a year. The book, "Advanced Bee Culture," is 50 cts. Both for $1.25. All new subscribers for 1892 will receive the December, 1891, issue free. Address

STRAY STRAWS

FROM DR. C. C. MILLER.

PUNIC BEES are threatening a libel suit in England.

ALPAUGH'S SECRET is now $2. I'd like to know, but no use trying. I couldn't keep it secret.

THE ILLINOIS STATE society entered an earnest protest against opening the World's Fair on Sunday.

THREE-SIXTEENTHS of an inch is advocated as a bee-space by no less authority than J. B. Hall, of Canada.

THAT'S RIGHT, Mr. Editor. Keep A. I. down in Florida and Cuba till settled warm weather, then he won't spring dwindle.

PROGRESSIVE BEE-KEEPER is the new name of the *Missouri Bee-keeper*. It can't progress any further in getting up a neat, clear page.

NOW THAT there seems a general tendency toward 4¼x4¼ as a standard section, it seems too bad to start up 4½x4½ as a desirable size.

SO IT'S A FEW, and not the mass of bee-keepers this side the line that are making trouble with the Canadians. I wonder, however, if those *few* are not the *other* side the line.

FURTHER NORTH, say in Wisconsin, although colder, may be a safer place for outdoor wintering than in Northern Illinois. The greater amount of snow there makes it safer for the bees.

BLACK BEES are best, in the opinion of the *White Mountain Apiarist*, and Italians are being boomed by editors and others. But isn't it a rather long-continued boom, Bro. Ellinwood?

THE TWO CANADIANS, Corneil and Jones, are having a lively tussle over bacillus alvei. Jones says it's in honey, Corneil says "no." There's lots of grit and ability on both sides. May the truth win.

COLOR, in the scale of marking the Italian bee, as adopted by the North American convention, counts 5 in a scale of 100. Doesn't it generally count about 50? I think there were some level heads at Albany.

CELLARING has one advantage—greater security against thieves. Two combs have been taken out of one of my outside hives this winter, and a Wisconsin bee-keeper has had 13 hives of bees stolen within a few years.

ALFALFA FIELDS don't, one tenth of them, yield honey, according to R. C. Aikin in a valuable article in the *Review*. They're cut for hay before full bloom, and it's only fields left for seed, or scattering plants, that yield the honey.

FOUL BROOD may or may not be as plentiful as it has been, but it exists in Illinois where its proprietors defy any interference; and if it should break out to-morrow near you, you'd wish a law to meet the case had been made a year ago.

DADANT'S METHOD of rendering old combs, as given at bottom of p. 26, is all right as far as it goes—mash 'em up fine when cold—but a very important part is left out. *Soak* in water, and then the broken cocoons can't absorb a good share of the wax.

HON. EUGENE SECOR edits the "bee column" of *The Farmer and Breeder*, of Cedar Rapids. He knows enough to make a good editor, besides being president of the Iowa State Society and of the North American, and a really nice man at the same time.

I'M GLAD that bright bee-keeper, Capt. Hetherington, couldn't stand it to keep in his shell any longer, but had to go to the convention at Albany. But I've never blamed him one bit. I'd rather be a recluse than to run a free tavern with an information-bureau attachment.

A BEE-SPACE—formerly it was ⅜ of an inch, now it is scant ¼. But doesn't it make a little difference where it is? Any horizontal space over the bees needs to be less than a perpendicular space to one side. Isn't the old ⅜ space about right still, between end-bars and end of hive?

THE *Guide* darkly hints that the life-members of the N. A. B. K. A. expect to have control of the World's Fair exhibits, and that outsiders may have trouble getting their traps on show. First I'd heard of it. But say, friend Hill, if that's so, bring on your things; I'll promise to get you in.

THAT DRINK on page 8 troubles J. A. Green. I think that drink's all right, Jimmie. The yeast is to make it good. So it is in bread. The effect of a quart, or, for that matter, a gallon of it, after it is "good for use," would be just the same as so much water sweetened with honey. Did you thought it was 'tosticatin'?

THE DADANT HIVE is very popular in France. The apicultural congress at Paris decided to change the size of the frame from 16.5 x 10.6 to 15.7 x 11.8 inches inside measure. Mr. Dadant, in *Revue Internationale*, very properly protests against having the name "Dadant frame" applied to any thing so different from what he approves.

FOUL BROOD, where it has been killed out and reappears again, F. Morel-Fredel, in the French *Revue*, thinks, may have been preserved by wasps, bumble-bees, or hornets, from which the bees are infected anew. He also thinks the disease may be acquired by sound bees working on flowers which have been visited by foul-broody bees.

Gladstone says: "I have always taken great delight in my garden, and do not think I shall ever be old enough to lose my interest in seeing things grow. If the season is propitious I frequently spend the half-hour before breakfast among my flowers." I wonder if that has something to do with his vigorous mental powers in his 83d year.

Queen-excluders under surplus-chambers, a correspondent of the *B. B. J.* thinks, are not needed over the whole surface of the hive, but only at the front and back end, and a thin board over the rest. He says the bees don't go up through the middle of the brood-nest, and the full-sized excluder gives much more room than is needed for bees to go up. Somehow I'm afraid the bees will not work quite so well over the board; but actual experiment only would settle it.

RETURNING SWARMS TO THE PARENT HIVE.

DADANT EXPLAINS HOW TO DO IT AND NOT HAVE THEM SWARM OUT AGAIN.

Friend Root:—The inclosed letter from J. S. Willard explains itself. Mr. W. desires that we should give in Gleanings the particulars of our plan of returning the swarms to the parent colonies to keep down increase. You will remember that this was mentioned in Gleanings for 1891, page 541, and called forth a number of inquiries from bee-keepers in different localities.

Messrs. Dadant & Son:—In describing your plan of keeping down increase by returning the swarm in 48 hours, you do not say *where* to hive the swarm in order to save the bees that have their new home located; and, also, would you hive them in an empty hive on starters? A friend of mine wanted me to write you for particulars about that plan of returning the swarms; and, in fact, I thought I should like it myself too, and very likely several of the readers of Gleanings would like to have you describe the plan more minutely; and if *you* think so, you can write a letter to Gleanings at your leisure.

Bedford, Iowa, Feb., 1892. J. S. Willard.

We wish to say, first, that this plan is not of our originating. We saw it first in the *Cours d'Apiculture*, of Hamet, published in Paris years ago. Hamet advised this plan more particularly for the secondary swarms. In those days of box-hive bee-keeping there was but little need of returning primary swarms to their colony. But we tried this method on primary swarms, and with good success. We notice, also, that a number of apiarists have tried it the past summer with fair results. Hamet says: "The swarm which is to be returned to the parent colony should be hived like any other swarm, and placed as close to the old colony as practicable. The next day, or the day following, the swarm should be shaken in front of the parent hive, just as is done in uniting several swarms together. They should never be returned the same day, as they would surely start out again in 24 hours. When they are returned after a lapse of time there is a fight between the queens, if the young ones are hatched, or the returning queen destroys the others in the cells."

Collin, in his book, "*Le Guide du proprietaire d'Abeilles*," advises the apiarist to place the swarm on the old stand and remove the old colony to a new location, waiting till the queens are all hatched before bringing it back. But this method has one objection—the swarm remains too long in the new hive, and raises brood in it, and this brood is practically lost.

The plan that we followed, and which we recommend, is to hive the swarm into an empty hive with frames and guides of foundation, exactly as if it were intended to be kept, and to place it near the old colony. In 24 to 48 hours, shake all the bees in front of the old colony. The combs that have been built in the meanwhile will never come amiss, and the few eggs laid will hurt nothing. It would be still better to remove the old colony from its stand, and return it when removing the swarm, and also to destroy the queen that has the least value—the queen of the swarm if very old, or the young queen if the old one is valuable. In fact, it is better that the old queen should remain, as bees are more likely to swarm with an unimpregnated queen than with a laying one.

We believe that this method prevents further swarming, only when the hive is in such condition that it would not have sent forth a second swarm. The issue of the first swarm puts an end to the swarming fever, the supplementary queen-cells are destroyed by the young queen, and one of the two queens vanishes in a duel when the swarm is returned. Unless the season is very favorable, the time for swarming passes away before the bees find out that they have been fooled by the apiarist, especially if he has provided ample room for their surplus honey.

As most of our bee-keeping friends well know, we are no longer comb-honey producers. For a number of years we have raised nothing but extracted honey, and therefore have no need of this method of preventing increase, for (Dr. Miller to the contrary notwithstanding) in an apiary properly run for extracted honey, there is no swarming to speak of. Every time that we have had swarming to any extent it was when we had infringed upon the rules that require that a colony of bees be supplied with a sufficient amount of empty combs ahead of need, during the entire honey season. It may be of interest to our readers to know how we found out the value of Hamet's advice on the return of the first swarm to the parent colony. It was in 1876. We had a number of colonies of bees in the apiary of our friend A. Daugherty, residing in Rocky-Run township, some 14 miles from us, in a very good honey-producing district. The season was a rushing one, and we were behind. The bees were swarming wherever they had not been provided with a large stock of empty combs. Friend Daugherty, who had some 80 hives of bees, including ours, found himself short of empty hives, and began harvesting the swarms in any kind of box, in nail-kegs, in flour-barrels. When our junior reached his apiary with a wagonload of empty hives, there were some 12 hives full of bees, that were not hives at all. So we began transferring the bees out of these boxes into the movable-frame hives, by shaking them out in front. The bees had been hived from one to three days previously, and had but very little comb built in their odd-shaped homes. Strange to say, they were so ill satisfied with the unceremonious transfer that every swarm left the new hives provided for them, and went back home to their parent hive. None of these hives swarmed subsequently; and as the latter part of the season was unfavorable they were the hives that made the best crop.

We hope the above is a sufficient explanation, and that Mr. Willard and others will find in it enough to pay them for the trouble of perusing it. Dadant & Son.

Hamilton, Ill., Feb., 1892.

[If we understand the matter the whole secret is this: The hiving of the swarm in a separate hive beside the old one and allowing them to remain there for a day or two gives sufficient time for the bees of both colonies to feel themselves as belonging to separate households.

Then when they are united there is war with the queen, and the swarming fever is forgotten. This is a valuable item, and we should like to get reports from others.]

THAT CANADIAN IMBROGLIO.

DR. MILLER OFFERS SOME NUTS FOR THE ONTARIO COMMITTEE TO CRACK.

Notwithstanding the fact that I am singled out as one of the evil few who were anxious to oust Canadians from the North American Bee-keepers' Association, the action taken by the Ontario Bee-keepers' Association came to me with a surprise as utter as it was painful. What! desire to be disassociated from that body of bee-keepers which includes in its numbers many whom I highly esteem, men whom I love as brothers! Have I so soon forgotten the kindly spirit shown by the Canadians at the Toronto convention? If, in reality, I had any desire to remain separate from them hereafter, then I should certainly have no word to offer in reply. Or, if the action of the Ontario were simply a withdrawal because further affiliation were considered unpleasant or unprofitable, then I could only regret the loss and submit in silence. But when false charges are made, even if they arise entirely from misconception, then, for the sake of those whose good opinion I value, I may be allowed a reply.

The first charge made is the feeling "on the part of some United States bee-keepers to regard and speak of the North American as a national institution." It is true, that the society was often called the "National" for short, and I think that is all the evidence there was of such feeling, or, rather, of such supposed feeling, for I am sure that for one I never had any other thought than considering the Canadians just as much brethren as the Georgians or Texans. Looking over the pages of the history of the society, characterized by Rev. W. F. Clarke as that "admirable compend" for which "we all owe a debt of gratitude to our friend Thomas G. Newman," I find it called the "National Society" in the minutes of 1878; and in 1884 a motion seconded by a Canadian, S. T. Pettit, appoints a committee "to consider what modifications, if any, should be made in the *National* Society." "Rev. Wm. F. Clarke, of Ontario, spoke at some length on this resolution. . . . He said it was first intended to call the society by the name 'National,' but at his request it was called 'North American,' so as to include Canada. It was often called the 'National Society,' but it would be more proper to call it the International, for such was its real character, and such he hoped it would continue." In all this it hardly appears that the term "National" was looked upon as any thing betokening any wrong feeling, and it is hardly possible that Mr. Clarke so considered it. As corroborating this view, Mr. Clarke, in a written address at the convention of 1890, said, "I do not know of any ill-feeling that rankles among us." So I think it looks pretty clear that Mr. Clarke himself being judge, there was nothing to complain of up to the convention at Keokuk in 1890.

It may be well, also, to mention that at Columbus, in 1888, the name of the society was changed to "International American Bee-Association." As no other countries than the United States and Canada were represented in the society, it certainly does not seem that the adoption of the name International contemplated driving out the Canadians. Moreover, the adoption of this name was at the instigation of Thomas G. Newman, who is held up as one of the bad few. Two years later the name was again changed to the present one, Mr. Clarke himself proposing the change.

I think it is pretty clear, therefore, that, up to the meeting at Keokuk, all was smooth sailing. At that meeting it was proposed that the society be incorporated. That incorporation was and is the head and front of our offending. The committee on organization and incorporation in their report, right in the very act of furthering the matter of incorporation, recommended that the constitution should read in its first sentence that the society "shall include in its territory all of the United States and Canada." Does that look as though they supposed incorporation would throw out Canada? It is true, that Mr. Clarke objected that incorporation would affect the international character of the society; but his thinking so did not make it so, and it was explained that there would be no abridgment of its powers or limitation of its scope by means of incorporation.

The Ontario report complains that at Albany the committee on incorporation vouchsafed no information as to the terms, conditions, or effects of incorporation, but confined themselves to the bald statement that they had done as they were bidden. Why should they say any thing more? They were directed to do a specific thing—to get an advantage for the society. They did as instructed, and then came saying, "We've got the advantage." What more was necessary?

The Ontario report recites that at Albany one of the committee, in answer to a question, was told that the association was now local, but its influence would be national. This does not agree with the printed minutes, in which E. R. Root replied to Mr. McKnight's question, "It is incorporated under a State law, but its influence is national."

Objection is made to the word "national." Now, if the mental machinery of others is like mine they would think of Ontario, New York, Illinois, etc., as all one, when speaking of the society, and the word "national," in that case, would have just the same meaning as the word "international." I feel pretty sure that Mr. Root and Capt. Hetherington both used it with that signification, and still more sure that Mr. McKnight so used it in his question, "Is not incorporating it under a State law making a local society of what was a national body?"

The Ontario committee says it has "come to the conclusion that Canada has no rights under the new state of things, and that it was not intended she should." The committee has simply come to two very false conclusions. I don't believe that a single man that favored incorporation believed that it would take away any of Canada's rights, and I fondly hope that some of my Canadian friends have still confidence enough in my word, vile offender though I am held up to be, to believe me when I say that I had not the most remote intention or desire to do any thing to make the rights of Canada less. I am very confident that the rest of the vile few were of the same mind.

The hint is given that the States other than Illinois suffer from the same limitation as Canada. Most assuredly they are affected in the same way, and yet it has not come to my knowledge that a single word of protest has gone up from any one of them. Surely, the committee ought to find in "the great body of American bee-keepers, which it believes are not responsible," and to which it tenders "assurance of continued fraternal good will, high consideration, and cordial regards"—surely among these these there ought to be found not a few ready to rise up in earnest protest against any wrong done to Canada and the States outside of Illinois.

Now, in all candor, let me ask what harm has incorporation done? What right, just tell one little, lone right, that Canada had before incorporation that she now lacks? In what way is the North American any less "broad and international" so far as the society itself is concerned, than it was before? Will the meeting in Washington be any more local than its predecessors? What single thing has ever been done by the society that it could not equally have done if it had been incorporated at its first organization? What single thing is there that it can not do in the future that it could do if it were not incorporated? Will any one of the four gentlemen who signed that report answer these questions? I am sure that room for their replies will be given in the same columns that admit the questions.

I have too high esteem for the sound heads and kind hearts of Canadian bee-keepers to believe that any misunderstanding, as I am sure it *is* a misunderstanding, shall lead to any permanent estrangement. The truth will come uppermost, and we shall know each other better.

Marengo, Ill. C. C. MILLER.

A BOUNTY ON HONEY NOT DESIRABLE.

THE OBJECT OF PROTECTION; CHEAP SUGAR, ETC.

Our prohibition friends have a good deal to say concerning special privileges granted by the government to the liquor-traffic. A class of "reformers" demand that the government shall provide buildings for the storage of agricultural products, and insist that they are asking no more than about what is now granted the liquor-traffic. Now, it seems that a few bee-keepers are disposed to ask that honey shall be granted special favors similar to those supposed to be granted whisky. Did it ever occur to these friends to account for the reluctance of whisky in accepting these special favors? Why! it requires an army of vigilant officials, assisted, in some instances, by Winchester rifles, to persuade the whiskey-men to accept these alleged special favors.

The object of a protective duty is to guard a domestic product against the liability of being crowded out of our own market by a foreign competitor. From Root's price list we ascertain that the prices of some grades of tin plate are as low now as they were three months before the "McKinley Bill" was reported to the House, and on no grade has the price been enhanced to the extent of the additional duty levied by that bill. To protect tin plate it does not necessarily follow that the prices which obtained two years ago shall be advanced or even sustained; but it is necessary to guard against a repetition of that kind of competition which quickly suppressed former attempts to manufacture the article in this country.

Yes, when sugar was admitted free the price to the consumer was cheapened to the extent of the duty removed; but does any one believe that a like reduction could or would take place in the prices of salt, linseed oil, and wire nails were they placed on the free list? Does any one know of a locality or of a country where manufacturers sell salt at 10 cents a barrel, or where consumers can buy linseed oil at 15 cents a gallon, and wire nails at $1.50 per 100 lbs.? When coffee was put on the free list, did the price, in spite of trusts, go down and remain down? I merely refer to these subjects to indicate the difficulties to be met in any attempt to formulate cast-iron rules concerning the effects of tariff prices.

The protective system aims to build up all important American industries; but, to date, the sugar industry has not built up to speak of —it's a going to. Now the beet sugar is making promises. The existence of this industry, at present, seems to depend upon protection; and as it has been clearly demonstrated that the consumer pays the full amount of the duty levied on sugar, and that the price of the domestic article, in this instance, is also enhanced to the full extent of the duty levied on the imported article, it seems that it would be better for our people to pay only the duty on the small amount produced here. Under the present law we pay no more to the producers of domestic sugar than we had been paying to them during the last two decades.

But is honey, under present conditions, entitled to bounty? To get it, it will require a much stronger case than has been made up yet; and you may rest assured that there is no immediate danger of being incumbered by a bounty on honey.

A few years ago strawberry-growers—some of them—were demanding protection against bananas and a few other foreign fruits. I believe their demand was not complied with; but strawberries are still grown, and the demand for them continues good. At present I feel like classing this demand for a bounty on honey with that demand of the strawberry-growers.

E. Springfield, O. R. M. REYNOLDS.

BOUNTY NOT DESIRABLE.

SEALED COVER, ETC.

An impression seems to have gone abroad (and I find it in last GLEANINGS) that the comb-honey industry is independent of the price of extracted honey. Let us not be over-confident. I find a class of customers who would rather have comb honey, but are willing to pay only about 2 cents per lb. more than the price of extracted. It would be only just, no doubt, to have a government bounty on honey; but I am sure all kinds will need it alike. But I fear the "Government Stamp" as a protection to bee-keepers (page 13) would prove a delusion and a snare, and so would the "trade-mark."

THE WINTER PROBLEM.

I believe Ernest and G. R. Pierce (p. 952) are on the right track. My top cushions are often very damp, and in this condition combs are apt to become moldy and bees sickly. If upward ventilation is the thing, why do bees always seal every thing except the entrance as tight as a drum? I think I should like your new Dovetailed chaff hive, only I fear the chaff wall is not thick enough for our climate. We require a thermometer which is very long at the *lower end.*

Then for the new-old system of wintering mentioned above, it would need a bee-space over the frames to take the place of the Hill device used under cushions; also several years' experience on a small scale leads me to favor Dr. Miller's idea of an inch or more under the bottom-bars. This, of course, would be impossible in bodies intended to be interchangeable with supers, but the chaff-hive body is permanent.

WHO IS THE INVENTOR?

It may be easy to determine who is entitled to the credit of introducing this or that improvement; but the name of the inventor may be Legion. Take, for instance, your new hive-rabbet. Not liking the sharp edges of your old rabbet, I several years ago devised the identical form which you have adopted; but not finding a tinner who had a folder which would make it, I continued to use "finger-cutters."

NON-BURR-COMB FRAMES.

I agree with M. H. Hunt as to double top-bars in modified Hoffman frames. They are *perfection* in preventing burr-combs, and excellent in other respects; and when made of one piece, with the bee-space cut out with a saw, as you suggested last spring (or was it longer ago?) they could not be very expensive or complicated. Then, too, the new comb-guide could be made the same as in your new thick-top frame. BURDETT HASSETT.

Bonair, Iowa, Jan. 29.

RAMBLER'S HIVE-HOBBY RIDING.

DR. TINKER EXPLAINS HIS HIVE AND SYSTEM, AND HOW HE CAME TO ORIGINATE IT.

It was possibly unintentional on the part of Rambler, in his sketch of hive-hobby riding, page 54, to convey a wrong impression to the public concerning my hive. The idea sought to be conveyed in hitching my hive to Heddon's is, that I have copied after or borrowed from the New Heddon hive. If I have an incorrect view of the matter, and it was intended on the part of Rambler solely as a bit of his inimitable and ever appreciated good humor, I shall hope he will set me right. I desire to state, however, once and for all, that my hive is not copied after the Heddon hive, and that I do not practice nor recommend any part of the Heddon system.

The hive I use and recommend is a Langstroth hive, and represents no principle not embodied in the Langstroth invention. It is constructed with the bee-spaces and the simple suspended brood-frames of the great inventor, that are now in use by bee-keepers the world over. It differs from the standard hive only in size; and it may be of interest to know why I made such a hive.

In 1881 Mr. Doolittle gave to bee-keepers the first published ideas on the subject of contracting brood-chambers in the production of comb honey. To him also belongs the credit of developing the idea, by writing several articles upon the subject, until many bee-keepers, including myself, were interested. About this time (1883, I think) Mr. D. A. Jones introduced queen-excluding zinc to this country, and the bee-keepers were not a few who saw that, if we contracted our brood-chambers, we should be compelled to use a queen-excluder between the brood and sections. So the new zinc came into immediate use, and I began contracting all of my hives used for swarms by means of the zinc. About this time I made the now well-known wood-zinc queen-excluder, and put it to use extensively. The proper size of a brood-chamber for a swarm to be worked for comb honey to the best advantage was soon determined. It was found that, if the brood-space given was too small, much pollen would go into the sections; and if too large, the bees stored a part or all of their best honey in the brood-chamber. After many experiments I decided that all that was necessary during the active working season, both for swarms and for full colonies, was a "brood-chamber for brood," as I have so many times stated in the bee-papers, and that such a brood-chamber contains about 800 square inches of brood comb. It is then not a half or a divisional part of a brood-chamber, as in the Heddon hive, although it is smaller than the standard; but it represents the utmost limit of profitable contraction, and requires an extra story for spring breeding. As I used a hive of this capacity long before Mr. Heddon made known his invention, and am also original in its use, I believe that my rights to it will be respected by the mass of bee-keepers.

For several years I made the hives with Quinby frames, but finally, about six years ago, changed to the suspended Langstroth frame without altering the capacity of the original frame used in my experiments. I have since used no other hive or frame.

I call it a "storifying" hive because it is made on the principle of the Simplicity and Cowan bee-hives that were so made that the stories could be piled one upon another as high as desired. In using the hive for comb honey the sections are always placed upon the first story; and any extra stories that may be on the hive are carried to the top of the sections. By conducting these operations at the proper time I am able to prevent swarming, as a rule; and if an occasional swarm does issue in an apiary it is very easily re-united with the parent colony, thus disposing of all undesirable increase. In this management I am also original so far as I know.

Thus it will be seen that my hive stands upon its own bottom, and is neither borrowed from Heddon's nor from any one else, nor is the management advised the same in any particular, except in so far as bee-hives have always been managed. DR. G. L. TINKER.

New Philadelphia, O.

[The Tinker hive, although shallower than the Langstroth, may resemble somewhat the Heddon hive; but from the reading of Dr. Tinker's book, the system of manipulating it is very different from the plan used by Mr. Heddon with his hive.]

COST OF COMB HONEY.

MR. DOOLITTLE CONSIDERS MR. TAYLOR'S FIGURES.

Along in the seventies, a bee-keeper living some three miles from here was afflicted with a cancer. He went to a distant city to be cured of the same. While away he wrote me that he wished I would go to his place and put his bees in the cellar for him, as it was then time of year for the bees to go in. I went and did as he requested, being gone from home half a day, for which I charged him $1.00. On his return I asked him if he found the bees in good shape, and he replied that they were in splendid order. He then asked me how much he was to pay me, and I told him. Although quite a wealthy man, he thought I had charged him too much, and said he could have got such a one, mentioning a man whose capacity people considered worth about his board, to have set the bees in for 25 cts. I said nothing at the time, but led him out about the curing of his cancer, and asked him how long the doctor was, all told, in taking out the cancer and dressing the wound. He thought that, if all the time he saw the doctor was put together, it might amount to about two hours. I then asked him what he had to pay him for taking out the cancer, and he said $50. I next asked him why he did not get "such a one," meaning the 25-cent man alluded to above, to take out his cancer, and thus save the extra $49.75 he had paid the doctor. He saw the point at once, and, without a word further, handed me out the dollar.

I was reminded very forcibly of this little incident in reading what R. L. Taylor has to say regarding the cost of comb honey on page 56 of a late issue of GLEANINGS. It seems strange to me that Mr. Taylor should be willing to so belittle our pursuit as to allow only $45 for an apiarist who has sufficient brains to do all the necessary work which 150 colonies of bees require during six weeks in the height of the honey season. Why! the man who has only brains enough to break stone on the highway is not asked to work that length of time for a penny short of $52.50, in York State, that being $10.50 more than Mr. Taylor allows himself, who is said to be a noted lawyer, a senator, and a man of unusual ability. I wonder if he would not have been mad if it had been said that the Hon. R. L. Taylor earned only $45 for the six weeks he represented his State at the capitol. And is not his time worth just as much in the apiary as it is in the senate or anywhere else? I do not see any need of this lowering the standard of our calling, that a large "*net profit*" can be published to the world. Where is James Heddon, that we hear no warning from him about putting the rosy side of bee-keeping before the world? Is the keeping of bees such a menial service that the one who works at the calling can be allowed only $1.07 a day and board himself, while the *profits* on that same labor amount to $10.50, should the season prove an extra good one? I protest against any such showing. He leaves out many items of cost, such as our bee-papers and books, time to read them, attending conventions, taxes on bees, hives to put the bees in, sugar for winter, feeders, and work of feeding, etc.

Let me try my hand at the matter, and let Mr. Taylor rest assured that I shall make no charges for *the fun* part of our pursuit, which he fears the "wife and children will not grow fat on." Interest on bees, and wear and tear on plant, $120; double interest on 150 Heddon hives, $54; taxes, $6; sections, $25; foundation, $30; shipping-crates, $40; hauling honey to railroad, freight, and commission, $125; bee papers and books, $5; attending conventions, $20; sugar for winter stores (10 lbs. per colony where the Heddon hive is used, as the combs are expected to be nearly empty in the fall), $70; time spent, as follows: Reading bee books and papers, attending conventions, feeding, making crates and sections, fastening in foundation, packing honey for market, taking bees in and out of cellar, and other manipulation, 40 days, together with 41 days required during the honey harvest, making 81 days needed during the year to properly care for an apiary of 150 colonies. This time at $5.00 a day (not an unreasonable figure for an intelligent apiarist), amounts to $405, which, together with the other items of expense mentioned above (which foot up $495), makes $900 as the cost of running an apiary *properly* for one year.

Now for the income: Seasons, or something else, seems to have changed; and where 50 pounds of comb honey was considered an average yield per colony 12 years ago, and 45 pounds five years ago, the average yield at the present time can not well be called more than 40 pounds, according as I have summed up our yields during the past three or four years. At an average of 40 pounds for the 150 colonies, we should have 6000 pounds of honey as the income from the bees, which, at 15 cts. per pound, would amount to $900, or the same amount that the cost was. Hence I conclude that the cost of a pound of comb honey at the present time is 15 cents, and all that it brings us over those figures is *net profit*. When I gave figures very similar to the above to the N. A. B. K. A., in 1887, according to the report of that convention, Mr. R. L. Taylor was the first man on his feet, and said, "In the cost of honey there are many points to be considered, and Mr. Doolittle has not mentioned all of them; for instance, the losses in winter and from disease. I think the prices given are *too low*." Italics are mine. I then called the average yield 45 pounds, and arrived at the conclusion that the cost of a pound of comb honey was 13 cents, and Mr. Taylor immediately arises and says it is "too low." What has happened on the horizon of his vision that has so changed his opinion during only about four years of time? I there allowed the man the whole year to work the bees at $1.25 per day; but if valuable time is to be used, as Mr. Taylor puts it, and a less number of days be spent, then $5 a day is none too much for *skilled labor*. G. M. DOOLITTLE.

Borodino, N. Y.

[This question is somewhat complicated, and there is plenty of opportunity for error and incorrect assumptions; and perhaps our correspondent, though usually so accurate, has laid himself open a little. A merchant, after a year's successful business, after deducting expenses, has a certain amount of profit. This profit usually represents the price for his labor. So in like manner the amount paid for ordinary labor represents so much profit to the laborer. It is not quite clear how Mr. Doolittle makes his honey cost 15 cts. His crop being sold, at a charge of $5.00 per day for his labor, he has $405 in pocket—all this made off the bees. This we regard as largely profit, although it would appear, from what Mr. Doolittle says, there is no money in comb-honey production for him. But Mr. Doolittle did, or does, as he has said at other times, all or nearly all the work himself, hiring no labor. Much of the preparatory work which he does himself at $5.00 per day could be done just as well by a girl or woman at 75 cts. or $1.00 per day; for instance, folding sections, putting in starters, filling hives - crates with sections, scraping sections after being filled, and much other work, could be done by cheap help. If his time is worth to him $5.00 per day it would put more money in his pocket to devote it entirely to expert work, leaving the non-expert work to cheap help. This would *save* him $4.00 per day for much of the work, and a dollar saved is a dollar earned.

Now with regard to the work in the apiary. We have no trouble in getting good apiarists—those who can do any thing among bees, such as producing a high grade of queens, or producing honey, for from $1.50 to $2.00 per day, and they will do it just as well as we, providing we supervise or superintend the work. The cost of doing certain kinds of labor should not be regulated by what *we* can do it for, but by what we can hire it done for, and yet have it done as well. If Mr. Taylor can hire his work among the bees done for $1.07 per day, under his direction, while he can earn by his profession from ten to twenty dollars per day, it is to his interest to do so. We can hardly see why, then, he ought to figure labor in his apiary at ten or more dollars per day, when, in fact, he can get it done for $1.07 per day.

A farmer once said, who valued his labor at $2.00 per day, that he couldn't make any thing raising crops because they cost him to raise them all he got for them. If he received cash to cover cost according to his way of thinking, the fallacy of this argument is shown by the fact that he pockets $2.00 for every day he worked on the crops just as soon as he received the cash.

From these and other considerations we can not see how Mr. Doolittle's honey costs him 15 cts. per pound. He doesn't produce honey or raise queens and sell at cost. He is, as we all know, a successful bee-keeper; and when he charges himself $5.00 per day for labor, and gets that much in return, he is getting good pay, or, if you please, profit. The fact that he has a beautiful and comfortable home, and something laid up besides for a rainy day, as he has told us, proves this. It is quite possible that Mr. Taylor may have figured the price of labor and the cost of colonies in Heddon hives too low; and it is possible that he has not allowed enough for the cost of incidentals. We would not, however, figure "going to conventions" in the cost of producing honey, for this is the "fun" part of bee-keeping. Reading bee-journals and bee-books is usually to be done at odd hours in the evening, and this really should not figure very largely in the cost.

It will be seen, however, that Mr. Hilton put the cost even lower than did Mr. Taylor. He is a careful and practical bee-keeper, and one who has made money with bees. We are glad to give his article right here.

HOW MUCH IT COSTS TO PRODUCE COMB HONEY

FOR A PERIOD OF TWELVE YEARS.

The cost of the production of comb honey, like the wintering problem, the grading of honey, and many other things in which latitude and locality are controlling factors, will never, in my opinion, be satisfactorily settled. Could I have made this report four years ago, when my average for eight years had been 75 lbs., I could have shown the minimum cost in this locality. But the past four years have reduced my average for a period of twelve years to 50 lbs. per colony. In making this report I shall mass the twelve years' effort into a single report; and while this (my home yard) has varied from 35 to 90 colonies, I find the average has been sixty, or the

Total number for twelve years	720
Pounds of honey produced	36,000
Cash receipts	$5,200

COST OF PRODUCTION.

Value of apiary	$3,600
Interest on same at 8 per cent	288
Cost of manipulation	360
40,000 sections at $3.50	140
300 lbs. foundation at 55c	165
3000 shipping-cases at 8c	240
Total cost of production	$1193.00
Cost of production per pound	$3\frac{3}{10}$c
Net profits in twelve years, with an average of sixty colonies each year	4007.00
Net profits per pound	$11\frac{1}{10}$c

I suppose this report will be criticised. Friend Taylor, in his very able report, places the cost of production, with an average of 50 lbs., at $5\frac{6}{10}$c: but he has a list of items of costs that are, with me, all included in the cost of production, as my work is done principally by students. The work of putting up sections, putting in foundation, packing honey in shipping-cases, etc., is all done during the honey season, or immediately at its close. Friend Taylor also figures his gross receipts at 15 cents, and deducts freight and commission from this, while my sales have averaged me 15 cents, freight and commission deducted, which would in part account for the difference. You will also see that my labor costs me much less than Mr. Taylor's. The work is all done with a system, and upon general principles—so much so that my students find much time for other work. In fact, should I give the apiary credit for what they help me in the supply department it would nearly pay their wages. Our manner of manipulation might be of interest, but would be out of place here. I admit there are other expenses in the apiary than the above—foundation for the brood-nest; hives and fixtures for the increase; but in the above we have made no account of queens sold, nuclei, full colonies, etc. While these come from the sixty colonies spring count, it is another account which pays for all these and leaves a margin.

Since commencing this report the January number of the *Bee-Keepers' Review* has been placed on my desk. I have stopped long enough to read an article from the pen of E. R. Root, and will profit by his advice, and make this report short. GEO. E. HILTON.

Fremont, Mich.

[We should be sorry to have this discussion stop right here, and we hope our bee-keeping friends will give us further data along this line.]

EXTRACTED HONEY.

EFFECT OF POOR QUALITY UPON THE POPULAR NOTION THAT EXTRACTED HONEY IS LARGELY IMPURE.

I got both a setback and an uplift from a grocer in Springfield the other day. I wanted him to help us out at our fair by offering premiums on honey extracted on the grounds. He said, emphatically, "No; it would not pay me or any one else. Exhibiting an extractor, even in operation," he said, "would have little or no effect in removing the largely prevalent opinion that extracted honey is generally manufactured or adulterated;" that the only way to do that is to produce and put on the market honey of first-class quality. He said good quality would sooner or later remove the prejudice against any thing. He cited butterine as an illustration. That, he said, is now made of such excellent quality that many prefer it to butter; that it is, in fact, *better* than half the country butter. I should not be surprised if that were so, that many Chicago merchants advertise, "We sell butterine." But much or all of the popular suspicion as to the purity of honey is due to its inferiority; and that a high standard of excellence would sooner or later remove that impression, we feel sure. He has handled considerable of my honey, labeled with my name and address, and he says that, after a trial, his customers cease to question its purity. The above reminds me that a lady acquaintance, who has been living in Chicago for a few years, was back on a visit last summer, and came to me for some honey. While here she told me she could hardly get any kind of honey there but extracted, and that was hard to get pure. I expressed my doubt as to its impurity as politely as I could; but she insisted that she had bought some she knew had been adulterated, because it was not good—it did not taste like honey. Then I told her it was probably honey that had been injured some way after it was extracted; that, to care for honey properly, is a very choice matter, and that I feared many who produce considerable of it were quite ignorant on that point. I admitted to Mr. B., the grocer, that honey, if ill cared for, would deteriorate until it would probably become inferior to the spurious article.

Of course, I argued with Mr. B. that an extractor in operation would prove a great educator; but I had to own myself convinced, that, to a great extent, what he said was doubtless true; and I take the above method of introducing the subject here. Is it not true, that a great deal of very poor honey is produced and marketed when it need not be so? I know an intelligent bee-keeper who said he kept his honey tightly bunged up in a barrel in the cellar, and thought it kept very well. This honey he afterward shipped to market. I would not risk storing mine thus. I never tried exactly that expedient; but some years ago I filled some waxed kegs with honey, bunged them closely, and left them on the ground for awhile—how long I do not now remember. At another time I had a stone jar full, into which I think a little water leaked; if not that, it was not sufficiently ripened when it was extracted. In both cases the honey became flat in flavor from a loss of its richness, and at the same time acquired a sharp, acid taste. To allow honey to absorb a little foreign dampness, especially if it is afterward exposed to even a moderate summer temperature, or to extract it while yet rank and watery, will always have that effect upon it. Hence honey can not be safely kept in a cellar—I doubt whether even in a cemented one, unless it is so sealed as to be proof against air and moisture. But if it is stored in a warm dry room it will steadily improve in body and richness. This second or third rate honey *may* do for use in curing tobacco, but not generally for table use; and it is very easy and natural for the consumer, ignorant of the nature and different qualities of honey, to conclude that such is adulterated. I once sampled some honey in a store, nicely granulated, that I would not give one cent a pound for.

Now, I submit, is there not a great deal of ignorance or carelessness on the part of large producers in caring for honey, or even downright dishonesty on the part of some in putting such honey on the market? And is not the abundance of such an inferior article, to a considerable extent, the ground of the prevalent belief that honey is largely a bogus commodity? I incline to think, from the evidence I have obtained, that bee-keepers are themselves to a great extent responsible for the state of things which they so much deplore.

PARTNERS IN THE HONEY-BUSINESS.

I saw in Mr. B.'s store some beautiful white honey in one-pound sections, put up in nice pasteboard cartons, bearing the name and address of some Smith, from somewhere in Vermont. He got it from a house in Indianapolis, and, freight charges included, it cost him a little over 15 cts. per pound. I wonder if it did not go through a commission house in New York, or some place else. I thought, "How many people made a little money out of that little lot of honey—a part of their living, if you please!" Of course, the grocer gets a little himself. Then the railroads between Indianapolis and Springfield got a little; the firm at the former city got a little; the railroads from Vermont got a little, the maker and printer of the cartons got a little, the manufacturer of the sections got a little, the foundation-maker got a little, and it may be a firm in New York and another railroad got a little. What a stir a little honey or a little hog can make in the business world! A wonderful fabric, this country—this world of ours! Query: How much did Smith get? Geo. F. Robbins.

Mechanicsburg, Ill., Jan. 25.

BICYCLE OR TEAM.

E. FRANCE SAYS A BICYCLE WOULDN'T DO FOR HIM.

Ernest R. Root tries to make us think that the bicycle is the cheapest thing to be used, in visiting out-apiaries. Well, for him perhaps it is. It depends altogether on why you are going to make the visit. If you have local help at the apiary to do most of the work, and you are just going to call to see how things are running, or are going to get a few queens to take home to fill orders, or something of that kind, then the bicycle is all right. But I can not see how it would do for me, or any of our large bee-keepers. We always have too much to take along. We usually make our first trips around the last of March or first of April—an inspection visit; then we carry a keg of honey, 150 lbs., and fifty 3-lb. feeders. I don't know that we shall want to feed, but we want the feed and feeders along, and must take the team. After this first trip around we make two or three more trips, before the extracting season commences, to see that all is right, clip queens, etc., and always take our keg of feed along. When white clover blossoms enough so the bees are making a living, then we take along the extractor and some help, so we can take out every drop of honey there is in the hives so it will not be mixed with the white honey. We *must* have a team. Then when honey-gathering is in full blast, and we expect to take out 2000 lbs. of honey per day, we have to go with two teams—one team to haul the honey, and the other one to haul the help, etc. We have two horses of our own, and hire two more at the livery. During the extracting season we have all the wagons we want of our own. We are also working a little farm of twenty acres, and have to have one team.

DO THE BEES OF THE LARGE BEE-KEEPERS USE UP THE BEES OF THE SMALLER ONES?

The small bee-keepers are apt to think that their bees stand a poor chance when there is a large apiary near them. When I first began to keep bees around about Platteville there were a great many farmers who had each a few colonies of bees, and some of them as many as 100 stands. Now there are but few who try to keep bees at all. How often I hear complaints about my bees like this! They say, "France's bees have robbed all my bees—stole all the honey, and killed all the bees. I can not keep bees any more. France gets them all." We have had poor seasons, and bees not properly cared for have starved out. But the blame all falls on my bees. In one sense, perhaps my bees have done some of the mischief, inasmuch as they have picked up the honey pretty close. But did not their few stand just as good a chance as my many? Of course, they did. Well, what is the matter then? It is all in knowing how to take care of the bees. Can we expect a man to prosper in any business unless he knows how to run that business? A great deal depends upon small details—little things that appear to be of no consequence. It is a small thing to look into a hive and see whether there is feed to last through the winter. "Why," he says, "I simply took off the honey that was stored on top in the boxes, and the bees have all the hive full below;" when, if he had looked carefully through the hive, he would have found that he had taken off about all the honey they had in those boxes; then the bees die for want of feed. Then he blames another man's bees for his loss, when it was his own ignorance.

In wintering our bees outdoors, what shall we put over them—a cushion or a honey-board sealed down tight? This is a question that I am asked to answer through Gleanings. I suppose that you are aware that we winter all of our bees out of doors—at present between 500 and 600 colonies. We have wintered outdoors most of the time for thirty years, and have had very good success. We have tried a great many plans to insure the safety of the bees. We now use a honey-board over the bees—that is, a board made of ⅞-inch pine, cleated at both ends to prevent warping, and large enough to cover the colony tight and let the bees seal it down with propolis. We do all that is to be done for the bees by the middle of September, then let the bees seal the board down tight, and don't break the sealing again until the first of April, and then only to see if all is right. I don't want a particle of air to pass up through the bees during the winter; give them some vent at the entrance, but none on top. When the honey-board is on and sealed down, place a cushion, 5 or 6 inches deep, over the honey-board, or fill the top chamber with straw. This top covering helps to retain the heat. Put your hand under this covering in winter, and the honey-board feels warm—in fact, warm enough to melt snow in the coldest weather. We have tried putting a six-inch chaff cushion on the bees below the honey-board; but that won't do, as the chaff in the cushion becomes wet, and the bees dwindle bad and come out weak in spring. I believe that the bees' instinct to seal up all cracks and openings in the hive is correct at least, as far as the top of the hive is concerned, for outdoor wintering. When you put bees indoors to winter, you give them an unnatural place to pass the winter, and they may require different treatment. I have no doubt that they do. In fact, I never learned to winter bees successfully in the cellar; but having, of necessity, to winter on summer stands, I have studied and experimented a great deal on how to winter outdoors, and I think we have the thing now down to a safe point. Use a large deep hive. If the L. frames use two stories, have the upper story filled with good honey. Put on a tight honey-board early enough to get it sealed down, with straw or other good packing above the board. Give them a good windbreak, and then let them alone until spring. A quadruple hive is better than a single hive. E FRANCE.

Platteville, Wis., Jan. 25.

[Why, friend France, we are afraid you did not read our essay very carefully. We did not recommend the bicycle for every one—only for the bee-keeper who runs one or two out-apiaries. In the spring, when we go out on the bicycle, we give the stores by alternating combs. By a little intelligent forethought, many things can be so arranged as to make it unnecessary to carry things on the wheel, even though it were practical. At the request of several friends I have presented the essay as it was read at the convention.]

BICYCLES VERSUS HORSES FOR OUT-APIARY TRIPS.

AN ESSAY BY E. R. ROOT, READ AT THE MICHIGAN STATE CONVENTION.

One of the obstacles in the way of establishing out-apiaries is the expense necessary to make the trips to these yards. That expense usually involves the keeping of a horse and buggy; and when it is further increased by bad roads for six months in the year (during which time the capital invested in the horse, buggy, barns, etc., is lying idle, to say nothing of the daily labor) it becomes quite a serious obstacle indeed. I have had experience in the horse-business, as some of you may know. I know what it is to have almost impassible roads for six or seven months in the year, during which a horse can not be driven either for business or pleasure. I know what it is during this time to clean the stable, doctor a horse for mud-fever, for a month or six weeks; I have experienced the lively sensation of being kicked clear across the barn, and then on my back, panting for breath, scarcely knowing whether I had a whole bone or not. I have been run away with a couple of times, and know how exhilarating it is to feel that your life is hanging on a thread. I know what it is to have horses get into bee scrapes, having had one horse killed in one such, as you may remember—a noble animal for which I was offered $175 that very day. I know something of the cost of keeping buggies, horses, stables, etc., in repair. After having had this experience, my ardor in the horse-business has gradually waned. I must make trips to out-apiaries; and to walk to them would be too slow; and to use one of my father's horses—well, they were always busy cultivating, or something of the sort, in the garden.

As soon as I sold my last high-flyer I forthwith bought me a high-grade Safety Victor bicycle; and most of you know the rest. After having ridden it several hundred miles among the bee-keepers of the East, I found it indeed a most serviceable horse for making trips to our out-yards. On arrival at the yard I could leave it leaning against the fence, and not be in mortal terror that the thing would be stung by a bee, and cut up some awful caper.

I am no expert rider, but I found that I could make trips to our out-apiary, on an average, seven miles, in about three-quarters of an hour. When I tried to do something real smart, I rode ten miles, bought an apiary of 80 colonies, returned home, all inside of two hours. As it took me about 20 minutes to complete the bargain, the total time on the road of 20 miles was a little over an hour and a half. But the roads were good. On other occasions I have made 30 miles in three hours; 45 miles in five hours. The latter distance was made over the hills of York State. Now, this, no doubt, may look like a big yarn to some of the uninitiated bicycle-riders; but I am stating absolute facts. I do not give these figures to boast, but simply to show what an average man has done with a machine after a little practice. Now then: It will be seen that the bicycle is a great time-saver in making trips to out-apiaries. No horse —at least very few—would undertake to make such time. "But," you say, "such rates of speed must be a severe strain upon the constitution of the rider." Experience in my case proves that it is not, but, on the contrary, it proves to be a wonderful tonic to the constitution. The muscles of the leg develop wonderfully. But how is it, you may ask, that a man can travel so much faster than the average horse? The cushioned tires, ball bearings, and the gearing, give him an immense advantage over his dumb friend.

Perhaps some young bee-keeper will say, "I would have a bicycle if I thought I could ride it." It is no trick at all to balance one. Almost any one can be taught to ride them in half an hour's time. Even our friend W. Z., I am told, mastered the machine in twenty minutes; but in order to make speed and cover distance, it takes a little time to develop the muscles, and learn a few nice points in guiding.

"But," you ask, "doesn't riding seven miles to an out-apiary make you very tired—in fact, weary — too much so to do a day's work?" Strange as it may seem, it does not. Riding is one sort of exercise, and working over the hives is another. A different set of muscles in either case is called into action. Most of the care of our out-apiary last summer devolved upon the writer personally. I have taken a trip down in the morning, worked all day, and come back in the evening, tired, perhaps, a little, but no more so than any one else who has done a full day's work. At other times, when I have had a spare hour or two, I would mount the wheel, run down to the apiary, diagnose the hives, and give such attention as might be needed to this or that colony, then return, after about two hours' work. Now, the point I am getting at is this: A bicycle can be purchased for less than the price of an average good horse. The repair might be fifteen cents a year; oil for lubricating the bearings, perhaps another fifteen cents. Outside of that there is no other expense. Place this balance-sheet over against that for the expense of a horse, barn, hay, labor, repairs, etc. Now see how your account will stand. Well, a young man can make his trips to his out-yards, on the wheel—yes, make nine-tenths of his trips in that way. How about hauling the bees home? As a general thing, a farmer in the vicinity, with his double team, can be hired to do the work for you—that is, hauling—for a crate of honey or a small consideration in money. He can also be hired to haul home your crop of honey, and bring back all the supplies that you may need. With a little forethought, all these things can be carried in a few trips. In the spring, for hauling the bees to the out-apiaries, if the services of a farmer are not available at that time, a livery may be hired at about two dollars a day. Ten dollars ought to cover all the expense of hauling for at least one yard, and possibly two. Even if it were twenty, this would be a great deal cheaper than taking care of a horse for one year, to say nothing of the other expense, first cost, interest on the money, and other risks.

If you are a bee-keeper and also a farmer, then the horse would be more serviceable. But the point I would urge, in a nutshell, is this: That a young man in a locality where the roads are not sandy, can manage a system of two or three yards cheaper with a good bicycle, supplemented by the aid of a farmer or liveryman, than he could to keep a horse, buggy, and all the other paraphernalia connected with the horse-business. I have tried the scheme for one year, and I think I know something of what I am talking about.

In conclusion, let me add that I do not advise the use of a bicycle for elderly men.

[The above we had not intended to publish in our own journal; but as there has been some inquiry as to what we had to say on that subject, we give it in answer thereto.]

THE HIBERNATION OF THE HONEY-BEE.

TRUE HIBERNATION EXPLAINED BY MR. P. H. ELWOOD.

Mr. S. Corneil, of Lindsey, Ontario, Canada, writes us that Mr. Doolittle's article on hibernation, page 45, is somewhat misleading, and hoped we might see our way clear to publish an article by P. H. Elwood, in the *Canadian Bee Journal*, page 531, 1886. This article, he says, was a "settler" when the subject was up for discussion several years ago. No one ever attempted to answer it. We have looked up the article in question; and as it seems to cover the subject so thoroughly we are glad to make the accompanying extract from it:

What is hibernation? Marshall Hall says, "Sleep and hibernation are similar periodical phenomena leading to similar results, and differing only in degree." As Dr. Hall is probably the highest authority we have on the subject, and as his definition has been accepted by all investigators, it would seem to be well for smatterers in science to look up the standard definition and accept it, rather than to coin another which shall be accurate only in measuring the want of knowledge of its author. The Germans recognize hibernation as a peculiarly deep sleep, and their name for it is *winter sleep* (See Barlow's *Winter Schlaf*, Berlin). Do honey-bees hibernate, or is the quiet of winter only a sleep, or has it passed beyond sleep into hibernation? Dr. Edward Smith says a man in deep sleep expired 4.5 grains of carbonic acid per minute; on the treadwheel, 43.36 grains per minute. A waking hedgehog yielded 20.5 times more carbonic acid than one in a state of hibernation. Thus we have a ratio between sleep and waking of 1 to 10, nearly; between hibernation (not profound) and waking, 1 to 20.5. If, instead of the treadwheel, we take walking at three miles per hour (26 grains carbonic acid per minute), which exertion would correspond more nearly with that of the hedgehog, we have a ratio less than 1 to 6. Carpenter says of the bee: "When breeding, the evolution of heat and consumption of oxygen takes place at least twenty times as rapidly as when in a state of repose." This is the same ratio that exists between the hedgehog's hibernation and waking. But, dropping these comparisons as illogical, we may note the number of inspirations and the amount of food taken during the winter, which proves conclusively that, in its winter repose, the honey-bee has passed far beyond the physiological limits of sleep into hibernation. You will notice by the definition, that, where sleep ends, hibernation begins—there is no "quiescence" between. The daily summer sleep of the bat and dormouse is a true hibernation. Dr. Hall says, "The quantity of respiration is inversely as the degree of irritability of the muscular fiber, the former being marked by the quantity of oxygen consumed in a given time ascertained by the pneumatometer, the latter by the force of galvanism necessary to demonstrate its existence." The capability of passing into a state of hibernation depends upon the capability of taking on an increased muscular irritability. Were the respiration diminished without the increased muscular irritability, death would take place from the torpor of slow asphyxia; and were the respiration increased without the diminution of the irritability, the animal would die from over-stimulation, as in those suddenly aroused from the state of hibernation." As such trifling causes as walking over the floor, touching the operating-table, etc., are sufficient to excite respiration, hibernating animals adopt various means of securing themselves from disturbance; and when the temperature approaches 50 ° they seek out their hibernacles in trees, caves, and burrows in the earth. It was found that hibernating bats died when subjected to the motion of a stage-coach for a couple of days. The same treatment would undoubtedly seriously injure a hibernating swarm of bees. It was that close observer, Mr. L. C. Root, who first called my attention to the injurious consequences of the needless disturbance of bees during their winter sleep. And every farmer boy knows how unwholesome it is to be suddenly aroused from a deep sleep to immediately participate in the active duties of the day. How comforting to the rising generation that the doctors now say the process of awakening should be a gradual one !

Hibernation differs widely in different animals. While possessing the same general characteristics, yet in no two is it exactly alike; and we must not expect the honey-bee, which differs so much from every thing else of the animal kind, to conform in every particular to the already observed conditions of hibernation. In some animals, hibernation is very profound; in others, not. I have already given an illustration of the latter. A hibernating bat, in a pneumatometer, consumed but one seventy-second part as much oxygen as one awake. The bat may be said to belong to the former class. In some animals, before the period of hibernation a large amount of fat is stored in the body. This hydro-carbonaceous deposit serves as a store of heat and force during that period. In this class of profound hibernators, the total loss of weight is sometimes 40 per cent, or fully as much as usually sustained in starvation. Another class of hibernating animals store their chief supply of food outside of the body, and awake at intervals to partake of it. The marmot, hedgehog, squirrels, dormice, etc., belong to this class. To this class we must assign the honey-bee, the honey being the stored supply of heat and force. Some of this class have a partial dependence upon the fat of the body, but it is not asserted that this is the case with the honey-bee. Some bee-philosophers, however, maintain that bees kept on a short allowance through the fall and supplied later for winter, do not usually come through so well. There is also a small school of physiologists who assert that all carbonaceous food must first be converted into adipose tissue before it can be useful for the production of heat and force. This applies *equally well* to the honey of the bee as to the quarts of oil consumed by the Esquimau. According to Dr Hall, the hedgehog, in a temperature varying from forty-five to fifty degrees, awakes to eat at intervals of two or three days, depending upon this slight difference in temperature. The dormouse, which sometimes hibernates in bee-hives, awakes daily in moderate temperatures. Dr. Reeves says, "Lower temperature begins at the surface of the body and gradually approaches the center." This central part, as Dr. Hall, Spallanzi, and others have proven, remains permanently at a higher temperature. In hibernation, as at other times, a swarm or cluster of bees must be taken as a unit. Bearing this in mind, it is, as we should expect, that the center of a hibernating cluster is formed of a higher temperature than the outside, as Doolittle, Tinker, and others have noted. Most bee-keepers have noticed, on suddenly dividing a cluster of bees in cold weather, that the outside bees are somewhat lethargic, while those inside are lively and apt to fly out and sting; while if any of these half-awake outside bees fly they appear not to have control of their movements, and fall to the ground.

The heat of reptiles is from four to fifteen degrees F. above the heat of their medium, while the heat of individual insects is from two to ten degrees more than that of the air. Therefore it can not be said that reptiles or solitary insects hibernate as warm-blooded mammalia do. The same may be said of the individual bee. It is only when aggregated in clusters that a high and independent temperature is maintained. Hibernation must not be confounded with torpidity. The *American Encyclopedia* says: "The torpor produced by extreme cold is very different from true hibernation." And again, in another edition, "Extreme cold will arouse a hibernating animal from its lethargy, and speedily kill it." We all know that cold arouses bees. These, then, appear to be some of the leading chacacteristics of hibernation: An activity similar to but less than in sleep, with diminished respiration, but increased muscular irritability; lower temperature, lowest at the surface of the body, diminished need of food, and, when stored outside of the body, partaken of only at intervals of awakening, loss of voluntary motion, but continuance of involuntary motion. As bees possess so many of the conditions of hibernation, it seems reasonable to conclude that they hibernate. * * * P. H. ELWOOD.

[The article shows much painstaking care in its preparation, and, without doubt, the statements are correct, from a scientific point of view. Hibernation – at least with the bee-keepers on this side of the line – was pretty well worn out years ago in discussion; but we trust there will be no objection on the part of our readers to our giving what is both interesting and valuable. We presume Mr. Doolittle meant the same thing, even if he did not state it quite as scientifically.]

THE WINTER PROBLEM IN BEE-KEEPING.

MORTALITY OF BEES FOR THE LAST FEW YEARS: WHO FIRST ORIGINATED THE IDEA OF A SEALED COVER? SPACE UNDER FRAMES IN WINTERING; VALUABLE FACTS BY G. R. PIERCE, THE AUTHOR OF THE NEW BOOK ON WINTERING.

Mr. E. R. Root:—In your review of the above book, page 952, GLEANINGS for 1891, you make one criticism which I think needs a reply on my part, which I do, not with the design of provoking discussion, but simply to arrive, if possible, at the actual facts of the case. The criticism I refer to is as follows:

"The author has evidently placed the percentage of loss beyond what it really is. Twenty-five per cent would be nearer correct; and, among intelligent bee-keepers, ten per cent."

When I first commenced the study in a consecutive manner—of the subject of bee-mortality in winter, I endeavored to learn something positive in regard to the approximate average loss among bee-keepers; but I soon found that the question was a most intricate one, and that no solution could be reached which would at once commend itself to the bee-keeping fraternity. The reason for arriving at this conclusion may be formulated as follows:

a. There are no statistics, State or National, in regard to the bee-keeping industry worthy of the name.

b. Even the reports of bee-keepers, as given in the periodicals (agricultural and apicultural), when taken as a whole are found to be utterly valueless when scrutinized closely and compared with previous reports made by the same person. In order to illustrate this assertion, let us take a supposed case, which may be verified by any one who wishes to be informed on the subject in question. Let us suppose that Mr. B. is an intelligent bee-keeper who has 100 colonies which were placed in winter quarters in good condition. About the first or middle of April, Mr. B. writes to GLEANINGS, giving his experience during the winter, and saying that his loss has been, say, only 5 per cent, which is undoubtedly true. But in the September and October following, Mr. B. writes again to GLEANINGS, tells of the prospect of the honey crop in his neighborhood, gives his experience and opinion in regard to some of the methods or devices used in honey production, and closes by reporting his yield at, say, 3000 lbs. from 75 colonies, *spring count.* Now, Mr. B.'s two reports, when taken together, show that 20 colonies have mysteriously disappeared. It may be that Mr. B. is a breeder of queens, or that the 20 colonies were sold. I have no doubt that many of the reports given could be explained in this way. There is no question, however, that very many —in fact, the great majority, of the reports given in the press are misleading in this particular regard—no figures being given of total loss —only that which is apparent at the opening of spring.

Now, I do not wish to be understood as reflecting upon the honor of the men who from time to time give their experience through the press. I believe they aim to give the facts as they understand them; but, owing to the practice of reporting losses as soon as the bees commence to fly, they virtually ignore the subject of *spring mortality*, and yet the loss during the winter months is a mere bagatelle compared with that occurring during the months of March, April, and part of May if the latter happens to be a cold month. It is only when the weather becomes settled, giving continuously warm days and nights, that the effects of defective methods of wintering are fully apparent.

Again, there is another reason why reports of bee-keepers are, to a certain extent, unreliable as data upon which to base an opinion of the percentage of loss.

Bee-keepers have just about as much human nature in their composition as any other class of people. The "prominent bee-keeper" of a community is looked upon as an oracle in all matters relating to bees, and usually he does not exert himself to lower this public estimate, but, rather, enhances it by giving greater prominence to his success than to his failures. He may not do this intentionally, but the result is the same nevertheless; he is judged to be *uniformly* successful — a conclusion which the facts, if known, would not warrant.

I have found it exceedingly difficult to get figures from some bee-keepers as to their average annual loss of colonies. There is no diffidence in giving information in regard to yield of honey, or increase in colonies; but when the subject of *loss* is broached, there is a disposition to dispose of it as of no matter.

Several years ago I was considerably amused by a conversation I had on the cars with a bee-keeper from Illinois. I was deeply interested in the subject of wintering bees, and the talk very soon drifted into this channel. I was soon given to understand that my fellow-traveler knew (?) all about bees, if not a little more than all. From his standpoint the wintering question was of no particular importance—was more the result of ignorance than an unsolved mystery; he had no trouble in wintering bees, and did not see why other bee-keepers should. Seeing that loquacity was his weakness I contented myself with listening, only now and then asking a question at a favorable opportunity. I learned a great deal from this man—so much that I could not mentally digest it; and when I asked him to explain, instead of doing so he suddenly became comparatively dumb, and, at the first opportunity, retired to another car. Now, this man was as well posted on bee-keeping as the average; but he was keeping bees from year to year, apparently ignorant of the fact that a large percentage of his colonies died every winter and spring, simply from want of proper care. I know this to be the fact, because, in reply to my interjected questions, he gave me the following information:

a. He had about 75 colonies; 5 years before, he had 60.

b. He very seldom sold bees—no buyers.

c. He never "took up bees," that is, destroyed them.

d. He usually doubled his number of colonies each year.

e. He seldom lost in wintering more than two or three colonies—quite a trivial matter.

The average reader can readily see the point. When I commenced to devote attention to the subject in question I supposed that 25 per cent was a fair estimate of the average loss of colonies in the Northern States; but after a careful comparison of reports given in the bee-periodicals, and from my knowledge of the usual rate of loss in my neighborhood, I am constrained to believe that the figures given in "The Winter Problem" are not in excess of the facts. It is true, that there are some apiarists who winter with very small loss; there are also seasons when this loss is comparatively small in some localities; but in a decade this does not cut down the figures to a very great extent.

PRIORITY OF DISCOVERY.

Mr. Massie, of West Virginia, in Gleanings of Jan. 15, page 52, is rather disposed to claim the honor of being the first to advocate letting the bees seal the covers for winter. Very well! I do not claim any discovery in that direction, for I know from personal knowledge that the idea is at least 25 years old, and I rather think it is as old as bee-keeping. When the Langstroth hive was first introduced in Wisconsin, the main objections urged against it were, that it was too shallow for the bees to winter well; and that the top, being loose, more or less of the warm air from the colony would escape. The objections were met, by those interested, by the argument that the loose cover could be securely sealed by the bees *after* the honey season was over, and that the hive might, with but little labor or expense, have an additional covering of hay or straw. There are hundreds of bee-keepers who have for the past ten or fifteen years kept bees on this plan.

Neither do I claim to have first discovered the method of wintering in cases as described in my book, though I first used it during the winter of 1882. The plan is a very simple and rational one, and is only an improvement on the old method of covering with hay or straw.

A careful perusal of my book, "Winter Problem," will show that the setting-forth of new methods or devices was not the object in view; in fact, this is just what I wish to avoid. What I have aimed to do is to explain *why* bees perish in winter, and thereby show what *conditions* are essential and vital to healthy bee-life.

There is a wide difference between knowing *how* a thing should be done and *why* it should be done. The former knowledge is acquired by experience—is empirical; the latter can be gained only by an investigation into the working of the laws governing the subject under consideration—is scientific. Empirical knowledge may often be acquired simply by the use of sight—and memory; but scientific knowledge can be obtained only by a study of the relation of cause to effect. Let me illustrate the difference when applied to some of the operations of bee-keeping.

I have noticed of late that several of our prominent bee-keepers recommend the use of a rim under the hive in order to have an empty space about two inches deep—this, of course, only during the winter. I believe Mr. Hutchinson has, in one of his articles on wintering, said that colonies prepared in this way seemed to do better than those placed directly on the bottom-board, but frankly admits that he is unable to explain why this is the case. Dr. C. C. Miller, also, in "Stray Straws," Feb. 1, gives a quotation from the *British Bee Journal*, favoring the use of the space below the frames.

If I remember aright, this plan was first proposed by W. F. Clarke, of Canada, about the time that he introduced his "hibernation theory," and, as soon as I found it convenient, I tested the plan thoroughly in the following manner:

Ten colonies were wintered on their summer stands, prepared as usual, the hive resting on the bottom-board, and ten were placed with an empty hive—frames removed—under each one. These twenty colonies averaged nearly equal strength in honey stores and bees.

When winter set in I noticed that, during every sunny day *after a cold snap*, the bees in those hives resting on the bottom-board would be busy carrying out dead bees. The colonies over the empty hives did not, of course, need to do this, and this gave me the opportunity to see that many more bees perished from the hives prepared in the usual manner than from those having the under air-space. All experiments made in this manner confirmed the claim made for this method of wintering; and had I been satisfied to let the matter rest at this point it would have been positive evidence to me that an air-space under each hive was an absolute necessity. But this was the *how* of the matter, not the *why*. The placing of the empty hive under the several colonies was simply following a suggestion which had been proposed by another person; the explanation of the phenomenon was quite another matter.

The first fact that attracted my attention was, that the greatest loss of bees from the hives lacking the air-space occurred in the strongest colonies, judging from the appearance of the cluster at the bottom. This was rather remarkable, and the reader might explain it by saying that these colonies contained the largest percentage of old bees; but this was evidently not so; for it is not likely that all the colonies so constituted would be found in one class.

Again, another fact was presented: The loss was greatest in those hives where the bee-cluster *touched the bottom-board*.

I have not time to set forth all the methods adopted to solve the question, so I will explain and set forth the conclusion reached.

Of all the hive walls, the bottom is the coldest, and its temperature approximates that of the external air; therefore, when the weather is very cold, say 10 to 15 below zero (F.), unless the hive is well protected, the bees touching this cold surface will become chilled, and this loss will occur to the colony at every cold interval until, by its losses, it is enabled to cluster well up among the combs and away from the death-dealing bottom-board. This explains, I think, what bee-keepers have generally claimed, that bees winter better on deep than on shallow frames; and yet I do not think that an air-space below the hive is absolutely essential; for if the top of a hive is kept warm as I have described in "Winter Problem," the bees will naturally cluster away from the colder bottom; at all events, no rim would be needed except under those hives in which the bees clustered in such a manner as to touch, or be quite close to, the bottom.

When I first commenced to keep bees the wintering question was, during the cold season, the all-absorbing topic; and yet none of the books treating of bees entered into a real practical discussion of this particular part of the subject; and, judging from some of the questions proposed in the query column of the *American Bee Journal* and GLEANINGS, I surmise that the beginner now fails to find comfort in the bee-keeping text-books of to-day or he would not ask such a question as, "*What is the proper temperature for a cellar containing 50 colonies?*" for he would know that a proper answer to such a question requires a knowledge of all the conditions involved in his particular case. The same temperature will not do for a damp cellar as for a dry one; and where the colonies are in warm, well-sealed hives, the air must be kept cooler than when they are in loose-top hives. It is for this reason that some bee-keepers keep their bee-cellars at quite a high temperature, while for my part I pay no attention to low temperature as long as water in the cellar will not freeze; in fact, I regard a thermometer in a bee-cellar as of just about as much real utility as four legs to a wheelbarrow.

Blairstown, Ia., Feb. 3. G. R. PIERCE.

[It is to be regretted that we have not more accurate statistics upon which to rely; but from those which have appeared in GLEANINGS in the last three or four years, the percentage of bee mortality, as nearly as we can ascertain, was lower than what you put it. Still, these statistics may have been very misleading.]

◆

SEALED COVERS FOR WINTER.

ARRANGEMENT OF HIVES IN GROUPS.

I have not been a bee-keeper very long. I am following the advice of the A B C book, to "go slowly and carefully." After transferring a colony from a box hive I set the hive bottom up, and found it was so thoroughly glued over inside that it would hold water as well as a copper kettle. This made me skeptical about absorbents over a colony of bees. It is not their nature to thus prepare for winter. I have seen hundreds of bees in autumn gathering gum from gum-trees, and carrying it on their legs like pollen, to the hive, but I have never yet seen them gathering forest-leaves, swamp-moss, or even straw, and carrying it to their home as a protection from winter storms. Now, your idea of sealed covers over the frames is right; that is the way the bees would have it; and if you can not put on the board in time for the bees to glue it, why not paint the under side with a solution of beeswax and propolis, and wax the edges well, then put on all the packing you desire, to keep the moisture and cold from getting to the hive?

There has been a great deal said in GLEANINGS lately about the arrangement of hives for convenience in handling in summer, and much is also said about different methods of packing for winter. I will give you my plan; and if you think it worth a place you are welcome to it.

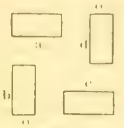

FIG. 1.

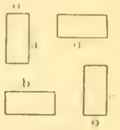

FIG. 2.

I arrange my hives on a pattern of Heddon's hive-stand, placing four in a group, as you will see by the diagram. Fig. 1 is placed for using the smoker in the left hand; Fig. 2 for using the smoker in the right hand. If I want to look into hive *c* I sit down on *d*, lay tools on *a*, puff smoke in at entrance *o* with left hand, take off the cover with the right hand; lay it on *b*, then I am ready for business. In Fig. 2 the smoker is held in the right hand, and the work done with the left.

For packing for winter I take a box made of any cheap lumber, that will answer, 3½ feet square, and about 14 inches deep; remove the hives from their stand; set the box on, and then place the hives in the box, in the same position as before, with entrances in the same place. Of course, four entrances are cut in the box to fit the hive-entrances. I then put in packing to suit my notion. Next winter I shall thoroughly paint boards with beeswax and propolis, and seal down tight on the frames before putting in the packing. M. M. RICE.

Dickeyville, Ind.

[We have grouped hives as you describe; but the objection to it is that the bees are flying in all directions. The S. E. Miller plan, which we recommend, see page 922, 1891, allows an alleyway for the bees for bee-flight, and an alleyway for the apiarist.]

◆

CLOSED-END FRAMES.

C. P. DADANT REPLIES.

Friend Ernest:—Allow me to correct a statement made by Mrs. Axtell, in the Feb. 1st number of GLEANINGS, page 97, saying that I never saw Mr. Axtell handle the closed-end frame. Mrs. Axtell is not to blame for the mistake made, for the reason that she was not present. The apiary where I saw Mr. Axtell handle the closed-end frame was that of E. A. Hanchet, Burlington, Iowa, May 8, 1878. You see that it dates back quite a few days, and it is not to be wondered that friend Axtell has forgotten all about it. As it was the first time that I had seen others than ourselves handle the closed-end frame, it made some impression on my mind. Some of our friends will perhaps wonder how I can so well remember the date. It is because this happened during the meeting of the Western Illinois and Eastern Iowa Bee-Keepers' Association, a very nice meeting, at which we first met Mr. Newman and many others, Mr. Axtell among them, though I believe we had met Mr. Axtell before; and I find the date in the old *American Bee Journal*. We were the guests of Mr. Hanchet; and at the dinner-hour a swarm came out and was hived. My remembrance is, that the queen could not be found, and that, as the swarm seemed restless, and it was necessary to make sure before going back to the hall of meeting, both the parent hive and the new hive were opened by Mr. Axtell. It was then that we both wondered how so practical a man as Mr. Axtell could advise the use of this hive.

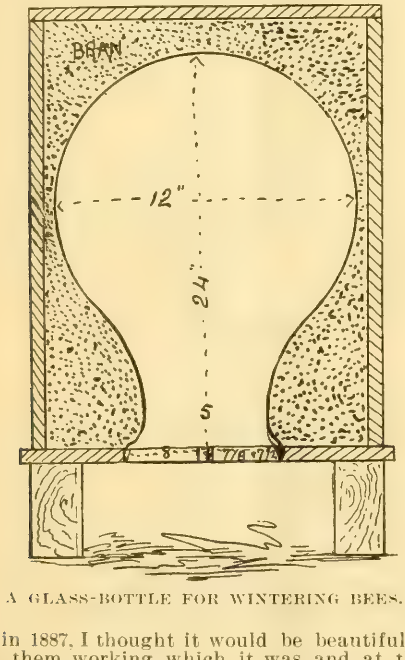
I have no desire to find fault with anybody's hive or frame; but I can not help noticing that even Mrs. Axtell acknowledges that bees are killed in this hive, even "with care." It is certainly more difficult to avoid killing bees with this hive than with the hanging-frame hive. But we all have our pets, and there are probably a hundred or more different styles of good hives now in use; and each owner would prefer his to any of the others, even if he saw them manipulated with greater success. C. P. DADANT.

Hamilton, Ill.

WILL BEES LIVE IN A GLASS BOTTLE ?

THE EXPERIMENT TRIED.

Five years ago I procured a glass jar, something in the shape of a pear, 24 inches high, largest diameter 12 in.; smallest, 5 in., and an eight-inch opening at the neck. I made a stand and box to cover it, and left an opening ⅞x7½ inches in the front. I have put a swarm in that jar every year for the last five years. They did very well until November or December, then they just died. Why? Well, "I don't know." There's the rub. At the time I first put a swarm in, in 1887, I thought it would be beautiful to see them working, which it was, and at that time there was a great deal of talk about upper and lower ventilation, so I thought this would settle the question.



A GLASS-BOTTLE FOR WINTERING BEES.

I said I put a swarm in every year. Well, there were never any bees living in it on the 1st of January. They generally died a little after the first cold spell, always leaving lots of honey, none of the queens over two years old. I have had blacks, hybrids, and Italians in it, but they all died. About the 1st of December I took a look at my bee-yard to see whether any tops had blown off. I found the bees in this jar dead, and combs very moldy. I cleaned it out and got four Mason quart jars of strained honey. Last fall this was one of the finest swarms. It had a queen one year old. Nov. 1st I had 116 swarms. They are all O. K. up to date, Jan. 9, except the jar. Why is it? I give my hives no protection whatever; but this jar was packed in bran. Of course, I shall try again and keep trying. In no year did the bees starve. They always had plenty of honey. J. F. LONG.

Scott Center, Mo., Jan. 9.

[We are surprised that the bees should have died as soon as they did, and the experiment was apparently a failure. It was J. A. Green, who once wrote about wintering bees in a large wide-mouth bottle, and here he gives something further on the subject.

UPWARD VENTILATION AND MOISTURE ABSORBENTS IN WINTERING.

INTERESTING SUGGESTIONS FROM J. A. GREEN.

When I first wrote on this subject, nine years ago, there seemed to be an almost universal belief that, to winter bees successfully, there must be a porous covering to the hive, with absorbing material above. The object of this, we were told, was to prevent the moisture generated by the bees from being deposited on the combs and inside of the hive in the shape of frost and ice. The current of air thus permitted to circulate through the hive, passing out at the top, carried with it the moisture. Under some circumstances this vapor-laden air passed out of the hive without depositing much of its moisture, in which case little immediate harm was done. Very often, though, the moisture was condensed in the packing material, sometimes making it quite wet, which was injurious, beyond doubt. The effects of this more or less pronounced draft through the hive, together with the wet packing, were most plainly seen in the spring, if the colony survived until then. The heat necessary for brood-rearing was kept up with difficulty, and colonies built up slowly. Strong colonies, of course, suffered least.

Having observed these things, I decided that the system of ventilation that had been found best for human residences was also best for beehives; namely, that the air to be removed should be taken out at the *bottom* of the room instead of at the *top*. I accordingly made my hives as tight as possible at the top, and left the entrance large enough so that the moisture-laden air might easily find an exit there. The result justified my expectations, and since then "upward ventilation" and "absorbents" have been things I have carefully avoided.

In a footnote to one of my earlier articles, the experiment you refer to on page 953 was proposed. Although I never wintered bees in a glass bottle, I did winter several colonies in tin cans and in other ways, by which I made sure that no particle of moisture could escape from the hives except at the entrance. These tests were entirely satisfactory, as all the bees so treated wintered excellently. They were never reported, because, by the time they were concluded, interest in the matter had largely died out, and other things occupied the bee-keeping mind. Since that time the current of opinion has been slowly changing, until now I think the majority of advanced bee-keepers would say that it is better to have the top of the hive sealed perfectly tight. Your experiments with hives having sheets of glass sealed tight to the top are interesting, because by them you can *see* that hives tight at the top and properly protected remain dry inside. I once had a colony of bees in a box hive with a glass side, and for over a month of the coldest winter weather they were close to the glass, which remained perfectly clear, so that I could see them at any time by removing the wooden slide over the glass. I used to look at them often, as I was anxious to learn the effect on them of disturbance in cold weather. They would readily respond to a tap on the glass, but paid no attention to the passing of trains only a few rods away. Even heavy charges of dynamite, used in blasting only a hundred feet away, produced only a momentary flutter of their wings, and, in spite of all the disturbance they were subjected to, they wintered well.

It is true, that there are some very successful bee-keepers who think a certain amount of upward ventilation is necessary. I think that all of these use very large hives, and carry on a system that gives them very strong colonies for winter. Such colonies are well adapted to resist the bad effects of upward ventilation, which is almost a necessity when such hives are used. A colony of bees can easily keep a small wintering apartment warm and dry, especially if no heat is allowed to escape at the top of the hive. But a large hive can not be kept warm. The moisture-laden air, instead of passing out at the entrance before it condenses, wanders off into the cold corners, and there deposits its moisture in the shape of frost. This, with very large and especially very tall hives, is unavoidable except by allowing a current of air to pass out at the top of the hive. In this, as in so many other things, different systems require different methods of management. I think a very large majority of practical bee-keepers will agree that a small hive, tightly sealed at the top, is best for winter, and especially so for spring.

Those who are interested in looking up what has been said on the subject will find articles by me on pages 42, 88, and 359, of GLEANINGS for 1886. The matter was brought up several years before, but was not discussed much until 1886.

A CORRECTION.

In my article on first page of Jan. 15th GLEANINGS, the word "undesirable" (second column, right margin) should have been "indisputable." The change of words, you see, makes a material change in the meaning. It is *indisputable* that the selling value of comb honey depends principally upon its appearance. This *may* also be *undesirable;* but that is not what I meant to say. Of course, in selling honey the *kind* and *quality* should be made known as far as possible; but when the price depends mostly upon appearance, let appearance be our principal guide in grading. If there is any dealer or commission man who can get more for a fancy article of dark honey than for a second or third grade of white, in markets where they come into free competition, let him stand up and be heard. J. A. GREEN.

Dayton, Ill., Jan. 26.

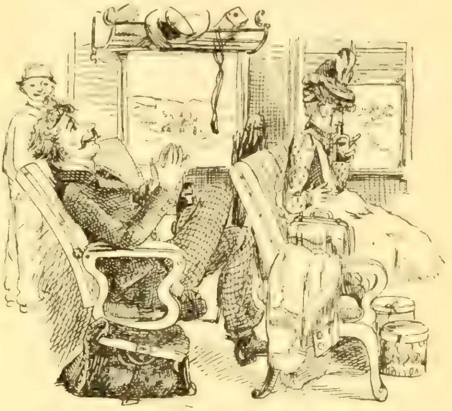
RAMBLE NO. 53.

FROM CHICAGO TO SALT LAKE CITY.

The next move on the Rambler's program was the purchase of a far-reaching ticket—a ticket that would land the possessor at San Francisco and the Golden Gate. As the train rolled out into the vast prairies of Illinois that bright July afternoon I felt happy again; and what a burst of poetry floated through my mind! Here it is:

I'm sitting in a double-jointed chair, jogging along,
Out o'er the vast prairie, praised so much in song.
Says I, "I do believe I'll have to ride and ride for iver,
To get beyond the smelling of that black Chicago River."

A female in a chair ahead had a bottle to her nose;
Says I, "Madam, it's a headache your having, I s'pose."
She riz right up, turned round with hand upon her liver,
And sneezed and hawked and spit, and snapped, "Chicago River."



RAMBLER'S REVERIE ON THE TRAIN.

I was right in the middle of the next stanza when the ticket-puncher came along and so distracted my attention that the burst poem has never returned. My elbow neighbor in the next reclining chair was a young man, posted on prairie matters, and gave me much information upon that subject. The shades of night put a stop to viewing the country, and we tilted our chairs back into the laps of those in the rear of us, and sought repose. My young friend had to get off the train about 2 o'clock at Cobble Hollow, somewhere in Missouri, so I kept awake on purpose to wake him up; so you may know that I felt outraged and defrauded when he awoke himself ten minutes before it was time.

Another young man came in and occupied his vacant chair; but I wasted but little time upon him, turned my face to the window, and slept.

Early in the morning Kansas City was entered, and an hour given for us to work out our salvation upon the delectable viands found in a railroad restaurant. I became quite well acquainted with my traveling companion during this hour, and, picking up a drummer who was going our way, we three had a very pleasant day of it all through Kansas. The length of this State will be realized when it is crossed; also the distance from the Missouri River to the Rocky Mountains. All day and all night we rapidly sped our way westward. The magnificent wheat-fields of Central Kansas were ready for the reaper, and the crop was never before so bountiful. All night it was Kansas soil we were upon. Away to the north the darkness of the night was broken by the flashing of lightning; a fearful storm was raging away over the distant prairie—not a mountain or hill to break the view. The electric display low down upon the horizon, and as far east and west as the eye could scan, presented a scene not soon to be forgotten. Morning dawned, and still upon Kansas soil; but the distant Rockies begin to appear; the line is passed into Colorado, and before noon the city of Denver is entered. Our stop is too short to let us see much of the city, and we are off again, passing in sight of Pike's Peak, through Pueblo, where we see the first adobe houses and the Mexicans; through the Royal Gorge and those lofty mountains we never tire of looking at. It was in these mountains that my new acquaintances left me; and for a time I felt lonely. Night again shut down upon the scenery, and, this being the third night on the rails, I slept quite soundly. In the morning I looked out upon the most desolate country imaginable—not a living thing in sight; not even a bush or a green spear of grass to enliven the red soil or the mounds and distant cliffs. One station passed was named Solitude, and rightly, for there was not a house or living being in sight. A stake and a cross-board with the name was all.

It was on this day's ride that I cultivated the acquaintance of a cowboy. He had been all the way to Grand Junction to attend a caravan.

Approaching the Great Salt Lake Valley the road follows the winding canyon and water-course. This water-course can be traced for miles by the narrow fringe of green on either bank, consisting of eucalyptus-trees and farm products; all outside this narrow fringe is dry and barren. The residences along this route are nearly all of the most primitive character; and I remarked to my new friend that people seemed to live in almost any thing, from a good house to a hole in the ground.

"Yes," said he, "and some haven't even the hole in the ground."

Just before entering the valley I saw the first Utah apiary. The hives were strung along in an irregular row, with stones on the covers. I wanted to get my Hawkeye to wink at it, but the train was in too great a hurry, and it was soon out of sight. After entering the valley, many thriving and pretty towns are passed; but Provo was the first having the real bustle and boom so readily noticed in the West. The train was full of smiling, talkative people in holiday attire. My cowboy friend left me at a previous station, and now a sturdy Milesian, who had lived in Utah 20 years, was discoursing to me about the great advantages of Utah, and especially of Provo, as a place in which to make one's life-abode. His remarks were strongly emphasized by wildly swinging his arm out of the car window, pointing out the variety of fruit-orchards, the enormous growth of alfalfa, and the general prosperity seen on every hand. I expected to see his arm irreparably damaged by coming in contact with a telegraph-pole; but he luckily escaped. His loud remarks called a young man to our vicinity, who wanted to sell real estate in Provo, the coming metropolis of the great interior basin. Arrival at Salt Lake City closed the importunities of these friends.

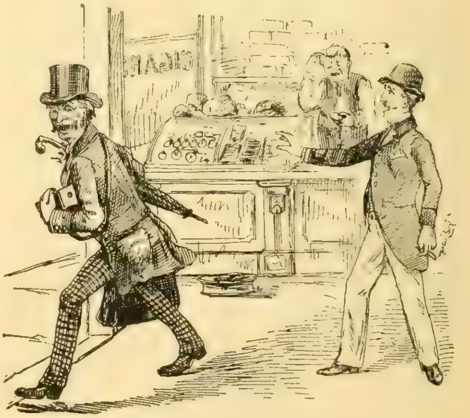
Salt Lake City has had such a reputation in the history of our country that I resolved to spend one day in this center of Mormondom. In the morning I sought the residence of Mr. John C. Swaner, and was disappointed when informed that he was some miles away managing a large apiary. I found the name of another person who kept bees, and sought the street and number, and was led out of the city where I could look all creation in the face. This was my first experience with the magnificent distances found in the West, and of which I shall have more to say when I get further. I devoted the rest of the day to looking over the business portion of Salt Lake City, and really fell in love with the place. The clear cold mountain water, purling like a mild brook down each street, has a special charm to it; and then the wealth of the water in producing so much vegetation for the sustenance of a large population, where, but comparatively a few years ago, there was nothing but barren sands.

A visit to the center of Mormon worship was my next desire. The magnificent temple is not yet completed. The Tabernacle, now used for worship, and several other buildings, are all within a high adobe-wall inclosure, and it is termed Temple Square, from which point all streets are numbered.

There is nothing ornamental about the exterior of the Tabernacle; in fact, its roof looks like an immense turtle. The interior is, however, noted for its elegance, its seating capacity (over 10,000), its wonderful organ, and its acoustic properties. A whisper, a rubbing-together of the hands, the dropping of a pin upon the altar-rail, can be heard in the most remote portion of the immense room. It was while perambulating around the Temple Square that the Rambler struck another friend. We discoursed pleasantly on all we saw, and then started down the street to see the beautiful house Brigham Young built for his favorite wife. My friend knew just where it was, and he was a wonderfully pleasant talker, this man from Denver. We had walked about a block when my friend said he must have a cigar, and stepped off the sidewalk into a little cigar-store, offering to treat; but when I declined he proceeded to light his own, and while doing so his eye caught several specimens of gold and silver ore on the show-case; and, being a mining man from Denver, he was immediately interested.

"Oh, yes!" said the man behind the case; "that's Utah ore, and here in the case are watches made from it; and in order to advertise our Utah mines and factory, we give any one a chance to draw an envelope from this box, upon the payment of $1.00. But," said he, "you two are strangers; just draw for fun, and see what you get."

The Rambler is always ready for fun in a quiet way, so I drew an envelope that entitled me to a gold watch. The envelopes were put back in such a manner that we could see the one I drew, and my Denver friend said he could draw the same one again, and bet $20 he could, and put up the money, and drew a watch. I suppose it was my turn to bet next; but up to this very point I had not a suspicion as to the nature of the men; but it came all of a sudden, and I exclaimed in a loud voice, "Bunco, by Jupiter!" My friends protested their innocence, but I suddenly left them to their own cogitations.



"BUNCO, BY JUPITER!"

In all the large cities of the East I had been on the alert for such fellows, and had frequently met them; but I was vexed to think that, away here in Salt Lake City, I should be so completely steered into a bunco-room.

That evening I pursued my way again toward California.

I learned from Mr. Swaner, that, in Utah, a modification of the American hive is used. Cloths are used over the frames, and much care has to be exercised in wintering.

Utah is a great fruit-country, and many apiaries are found in the orchards. Fruit culture and honey production thus go hand in hand, as they should. RAMBLER.

ANTS, PLANTS, AND BEES.

CURIOUS WAYS IN NATURE'S ECONOMY.

The following, sent us by Mr. P. H. Baldensperger, our correspondent in the Holy Land, is a translation made by him from a German periodical. It contains so many points of interest, well authenticated, that we believe our readers will be pleased and benefited by its perusal.

It is a well-known fact, that plants offer to bees, butterflies, and flies, the delicate nectar. In return, the insects unconsciously fertilize the flowers by carrying the pollen from one to another. But very often the insects, forgetting their duty, instead of creeping into the flowers simply cut open the flower outside the corolla, where the nectar is deposited, thus carrying away the sweet without touching the anthers, and so omit the fertilization. The bumble-bee finds it a good deal easier to cut open the tube of a red-clover blossom than to creep into the bottom of the flower about ⅜ of an inch deep. Darwin found almost every flower of a kind of heather, *Erica tetralis*, cut open in this way, and the honey carried off. But this way of robbing, contrary to nature's design, is very tiring too, as is reported by Prof. Magnus, who observed bees on the lion's-mouths (*Antirrhinum majis, L.*) trying the experiment, but they could not hold their position long on account of the evenness. They stopped only a few seconds and had to fly further, while otherwise they would stay a minute or two inside the flower, and by degrees they found plenty inside, and would again try to cut open the plant. Quite a number of tropical plants have a special preventive system against such culprits. According to Dr. Burck, of the Botanical Garden in Buitenzorg, Java, many plants have ant-guards against these robbers. Plants and ants are on friendly terms, as is known by divers kinds of South American trees which have numbers of protecting ants at their disposal, and they are fed liberally, and are ready to fight the leaf-cutting ants. They do their business very thoroughly. According to Dr. Burck's observations, the ant-guard system is enlarged in a very peculiar way. The enticement by which these plants gather the ant-guards around them consists in the secretion of honey outside the flower at the corolla, just at the point where the danger is apparent; consequently there are already some busy ants licking this secretion. The honey-glands, where this is secreted, are called the outer nuptial nectaries, to distinguish them from the inner ones, as they are not meant for fertilization. As soon as a bee observes the ant-guards on the outside it enters the flower in the natural way. Should it venture among the ants, it would be immediately laid hold of by its antennæ and legs, and it would be "done" with her. Besides this, it is seen that flowers without this guard, as the *Fragræa oxyphylla*, of the *Loganiaceæ* order, possessing no extra-nuptial nectaries, have 99 per cent of injured flowers, done by the carpenter bee (xylocopa). Another kind, *Fr. crassifolia*, has a few nectaries, on which Mr. Burck found only 70 per cent injured. But *Fr. littoralis* has more such nectaries, and only 40 per cent injured. Dr. Burck remarked, moreover, that a carpenter bee which had cut open 20 or 30 blossoms of the *Fr. oxyphylla*, and tried *Fr. littoralis* in the same fashion, had to give up at once and enter the flower on account of the ant-guards, though the three kinds of *Fragræa* resemble each other in shape, size, and color. Several such plants even provide their protectors with lodging, in shape of a recurved ear-shaped booth, affording shelter to these ants. Very often they also furnish these soldiers with ammunition — bread growing out at the flowers, having an albuminous and nutritious substance.

Thunbergia grandiflora more liberally feeds quite a number of ants the year round with such aliments; consequently the carpenter bee never approaches the outside of these flowers, but is obliged to look out for its business, and take the natural way.

PH. J. BALDENSPERGER.

Jaffa, Syria, Jan., 1892.

MANAGEMENT OF BEES IN TEXAS.

HOW L. STACHELHAUSEN DOES IT.

On page 893 of last year's GLEANINGS, Mr. A. C. Brown, of Smithfield, Texas, asks for information how to double his 45 colonies; and the answer of E. R. is just what we should expect from a bee-keeper with experience in the Northern States. With my experience in bee-keeping in Texas I would advise as follows:

Keep your colonies in the one-story hive, and let them swarm as they please. If you get small after-swarms, put two or three of them together in one hive. In a good year you will get as much honey, or more, from the swarms *and* the parent colonies, than you would do if the old colonies had not swarmed out at all. If the spring is not favorable your bees will not swarm much, and then it is better if you do not increase at all. Do not divide or make artificial swarms in any other way. To the new swarms you give no comb foundation, but starters of foundation about one inch wide, securely fastened to the comb-guides. Do not fuss with stimulative feeding, spreading brood, etc.; it does not pay in Texas. Of course, you have to feed your colonies, if they are short of stores and no honey is coming in; but, so far as I know, the bees will gather pollen in the spring anywhere in Texas. If the main honey-flow commences, do not fail to give plenty of room to every colony in an upper story; and now I would recommend full sheets of foundation in wired frames.

I have to explain to other bee-keepers why I recommend this way, so entirely different from the rules generally adopted in the Northern States. E. R. says, very correctly, that it is not the large number of colonies that brings the profit, but the rousing heavy colonies; but it is certain that two such strong colonies can do more than a single one. In most localities in Texas we have a moderate honey-flow from early spring till the end of May, and then commences our main honey-flow from horsemint. The bees swarm six or eight weeks before the horsemint is in bloom, so it is in good time for the swarm as well as for the old colony to grow to a rousing big colony. Just before swarming time the hive is full of bees; and if swarming is prevented in any way, the number of bees in this hive will increase very little if any. So it is plain that, in similar circumstances, it is more profitable to increase the colonies than to prevent swarming. True, we have some bad honey years, and the last three years in succession were such in my locality. This is the reason I did not recommend artificial increase. If the spring is so unfavorable that the colonies do not build up very fast, and consequently do not swarm, we should damage our colonies by artificial swarming. These swarms would be in a poor, starving condition; and if the horsemint will give some honey, swarm and parent colony are not strong enough to give any surplus. We may be glad if they store enough honey to pull through summer, fall, and winter. If the colony remains undivided it will give more or less honey in even a bad year. It takes an experienced bee-keeper, who is acquainted with his locality, to decide when artificial swarming shall be practiced and when not.

I recommended the giving of starters to new swarms only. After many experiments with combs and full sheets of foundation I settled on this practice, and recommended it for many years in the *Apiculturist* when all the other bee-keepers of the United States used and abused foundation. The reason, and my ideas about wax-secretion, I will give in another issue.

MY MANAGEMENT.

This, at swarming time, is the same. I work for extracted honey, and use large hives to make use of all the laying capacity of any queen; but nevertheless, my bees swarm. In the home yard I take the natural swarms. In out-apiaries I make artificial swarms if the spring is favorable. If the spring is so unfavorable that the bees do not store any new honey, but use up some of the old stores, it may happen that a sudden honey-flow may cause my colonies in the out-apiaries to swarm, and I should lose them. To prevent this I set one of my shallow cases with full sheets of foundation under every hive (in the out-apiary), and one of the brood-cases without queen on top over an excluder. This prevents swarming for at least two weeks; and if the conditions change I can make artificial swarms of them just as well.

When the horsemint-flow is over, and all the honey extracted, and I do not wish to increase the number of colonies, I reunite. This is done very easily. I set the first hive with comb, brood, bees, and queen, on a new stand, and the second one on top of it, without any ceremony. I let the bees decide which queen they want. The old bees will fly back to the old stand, and, finding no hive there, will unite with some neighboring colony. If some of them are not accepted it is no loss for me. They would die before winter, and there is nothing more for them to do this year. According to my observation, very few are lost this way, but are usually accepted. Both colonies losing their home, the old bees are not inclined to bite or fight. They unite peaceably, and I do not remember that one of these colonies became queenless. I call this a short cut. Thus I have a great force of bees in the main honey-flow, and few bees when they use up their stores. I let the bees build up to a strong colony, and, if possible, to even *two* strong colonies, and have only one colony all the rest of the year. But I like to have this one colony strong all the time, because a weak colony in the fall will not be stronger in spring, and a weak colony in spring does not grow fast enough in even a good year; while a good colony with a good queen will be a rousing one in a very short time without any fussing, such as spreading the brood, stimulative feeding, etc., and this is another *short cut.*

L. STACHELHAUSEN.

Selma, Texas, Jan. 30, 1892.

LADIES' CONVERSAZIONE.

THE APPEARANCE OF HONEY IN STORE WINDOWS.

MISS WILSON MAKES A GOOD SUGGESTION.

I feel very much aggrieved, and my special grievence is with commission men this time. I wonder why they don't make their honey look a little more attractive. In passing down South Water Street, Chicago, I saw very little, if any, honey that looked very tempting. Perhaps I don't know very much about the circumstances, and it may be they were making the very best display they could with what they had on hand. It is very easy to find fault.

However, I know that one house might have done better, for they had some very nice honey upstairs, while the display in the window was very poor. The room upstairs was dark, and the honey could be seen only by scratching a match, or by the use of a lamp. The reason given for not having a better display downstairs was, that they were expecting a very much nicer lot of honey in a few days, and were waiting for that.

It may be that it was a very inopportune time to visit. Perhaps they were all waiting, expecting something nicer. I hope so, I'm sure. I hope they got it, too, and made their windows look so nice with it that people passing felt they wanted some of that honey right away.

I know that commission men have a great many obstacles to contend with, and not the least of these is a lack of room. With much of the honey seen, the fault was not with the commission men, as no amount of painstaking on their part could have made it look attractive. I only wondered if it was the best they had on hand. If so, the trouble was with the producers, and they were to blame for sending it to market in such shape, and ought not to complain if they did not get a good price for it, as much of it could not have gone any higher than fourth grade by either the Chicago or the Albany grading. To be sure, some sections in some of the cases might have passed for first grade, if they had not been mixed with the others. Some cases shown were mostly nice, white honey, but several sections containing a good deal of pollen had been put in. There were other cases containing sections of beautiful white comb and honey, but a few of the sections were soiled, and a few containing honey-dew had been put in. Now, the commission man was not to blame if he did not get a good price for that honey. Putting the bad in with the good did not bring the bad up to a higher grade, but did bring the good down to a lower grade, and the producer has no right to expect the commission man to assort his honey for him, putting it in the grade where it belongs. He must do that for himself, or be willing to take the lower price his honey will bring on account of the shape in which it is put up.

I must say my fingers fairly ached to have some good honey with which to arrange some of those windows, to make them look attractive. When we are getting our honey ready for market, we take a great deal of pains to pile it up to look nice just for our own gratification, although it is going to stay there only a few days, and its looking nice will make no difference in the price to us. This year we piled the cases all around the sides of the honey-room, glass side facing us, and, when ready to ship, we had a room completely walled with honey; and unless you have tried it you have no idea how nice it looked. Of course, commission men have not the same chance, as they haven't sufficient room; but couldn't they do something toward it? Emma Wilson.

Marengo, Ill.

SOME NOTES ON WINTERING, ETC.

WISE HINTS FROM MRS. AXTELL.

I wonder how the friends at the Home of the Honey-bees, and also others of our bee-keeping friends, manage to keep their bees in the cellar cool enough this warm December weather. We have 122 colonies in our cellar, 20 x 20 feet, under our house, and no fire above, except at one corner. They are flitting out quite a good deal. We might open one or more windows which we plastered up, expecting a cold winter; but Mr. Axtell thinks if he does open them he will have them to plaster up again in a day or two. They now have one window and a door, and a sub-earth ventilator, all opening outdoors.

I can't help fearing that one reason for so many flitting out is honey-dew; and yet I can't see that there are many more on the floor under such hives than there are under the hives where fed on sugar syrup, as those fed on sugar syrup are marked for the weaker ones, and are put in the center of the cellar. But surely if this great waste of bees goes on all winter as it has thus far, the colonies can't be very strong by spring unless they rear brood in the cellar; and yet, unless there were a good many bees per colony, I don't see how they keep the warmth of the cellar to 42 and even to 46 and 48. At 42 they don't flit much. Last night it was above 50 for the first time. I don't know but it would have been better to put in fewer colonies. We have a large entrance by raising up the front board an inch or so; and this winter and last we have left out the chaff, with the honey-board on top of the bees turned over from what it was in the summer when on top of the surplus.

I look for a great loss of bees this winter, both in our apiary and throughout the West.

There seems to be no royal road to prevent bees from swarming. The devices all cost too much to come into general use, and will be partial failures; but out of this agitation something will assuredly grow. Except for the loss of time to the bees I would rather a few would swarm than to fit swarm-catchers to each hive and have to remove them again in the fall, and no swarms issue.

For my part, I think where the greatest failure in bee-keeping is, is in not getting the colonies strong enough to swarm, and the fault is away back the fall before. We always get a good crop of honey when we get lots of swarms; and if we could only do with our bees as well as we know how, they would pay us better.

Tell the lady who lost so many of her chickens from cholera to keep copperas in their drinking-vessel—about a tablespoonful to a pail of water—and give them plenty of sharp gravel. If they do not have any, pound up broken crockery and feed them. Also burn corn and feed them as charcoal. A few chickens will keep healthy without much care; but when one attempts to raise a large number they need a great deal more care to keep them healthy. An ounce of prevention is better than a pound of cure among poultry. Mrs. L. C. Axtell.

Roseville, Ills., Dec. 19, 1891.

CONVENTION NOTICES.

The 9th semi annual meeting of the Susquehanna Co. bee-keepers will be at Ballard's Hotel, in Brooklyn, on Thursday, May 5, at 10 A.M., at which time the officers for the ensuing year will be elected. All are cordially invited.

H. M. Seeley, Sec., Harford, Pa.

The Cortland Union Bee-keepers' Association will hold its annual meeting in the W. C. T. U rooms, Cortland, on Tues., Feb. 23. All invited. M. H. Fairbanks, Sec., Homer, N. Y.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

FOUL BROOD RAGING IN NEBRASKA; AN EARNEST APPEAL FOR ACTION TO STAY ITS PROGRESS.

I send you by this mail a price list sent to me. Look on pages 30 and 31. You said at the Albany convention you thought foul brood was diminishing. If the operations of some of the bee-keepers of Nebraska are a fair sample of the country, then I beg to differ with you. Here is a price list published here, offering to take bees in exchange for supplies, probably to be used in filling orders. Here is a section of country that I believe it would be hard to find one apiary in that is free from foul brood. I honestly do not believe there is one. Here is a little city where there were rotten combs thrown out in the street last summer. This is a regular hotbed of filth and corruption as far as bees are concerned. I find it impossible, on account of diseased robber-bees of neighboring bee-keepers, to keep my bees entirely free from it, although I can easily keep it in check so that it does not hurt them for honey-gathering. We have the genuine article here—at least, Prof. Cook so pronounced the samples I sent him last June. Can you deny that the Canadian law would be a good thing for these parts, with a man at the head who knows the disease in all its stages, with nerve enough to enforce the law without partiality? I do not believe that all the bee-keepers in Nebraska are dead in the shell. It is about time some one made a move in this matter. Are we all waiting for each other? If so I will start the ball rolling. We have a State law on foul brood, but it is perfectly worthless as it stands. It would do very well if it had only a little intelligent tinkering done to it. Elmer Todd.

York, Neb., Jan. 28.

[We said at Albany, that, so far as we could judge from reports, foul brood was not only diminishing in the United States, but that there was very little of it. Our remarks applied to the whole of the United States, without reference to any particular State; and so far we still insist on the truth of the statement. Foul brood may have gotten a bad start in Nebraska, and bee-keepers of that State should be up and doing at once. See that the State law is amended so as to be effectual, and then follow the example of the Canadians, and wipe out the pest.]

THE IMPROVED HOFFMAN FRAME; OBJECTIONS TO V'ING THE SIDES OF THE END-BAR.

I see that Dr. Miller has ventured to criticise your new Hoffman frame in Gleanings of Jan. 15th. Now, my experience with that frame, in regard to those V-shaped end-bars, is just as he surmises; that the bees will fill the space in the V-shaped end-bar with propolis, so as to make them a nuisance; at least, that is what they will do in Northern New York.

The first Hoffman frames that I used were made that way, and I was obliged to discard them on that account. I then made them with straight edges, when I had no trouble as long as they were kept close together; but I could devise no way to accomplish this except by a follower at the sides; and as my hives did not admit of any contraction, I did not experiment with them.

The Hoffman frame, or any other closed-end frame, must be held firmly together to prevent the bees from propolizing the joints. I do not believe it can be accomplished in any other way. I found that the least separation would start them; and then, if they were not repeatedly scraped, they would soon be so that I could not get all the frames into the hive.

Now just a word as to that tin rabbet that you illustrate in the same issue of GLEANINGS. That is a good thing. That is the only commonsense tin rabbet that I have ever seen; but, hold! it is identical in every way with the one that I devised some three years since, and failed to get you interested enough in to make me a supply for my hives when I was making them all over new. If I could have got you to make them for me then I would now have all of my 120 hives fitted with them. I can not but think that you might save us bee-keepers many dollars if you pursued a different course than you do sometimes. It would certainly save us much trouble and anxiety.

I do not know that I understand how your new top-bar is intended to be at the ends; but I found that it was necessary to have a bee-space at the end of the bar to prevent the end from being fastened to the hive. This also allows the frames to be moved endwise in putting them together, and shoving the bees out of the way. GEO. A. WALRATH.

Norwood, N. Y., Jan 21.

[That is what we want, friend Walrath—testimony for and against the V'ing of the end-bar. We saw its great advantage in so many places in York State, and were assured on every side that propolis did not make any serious trouble, that we did not regard it as an experiment or an unwise move in putting the V on the end-bars. Perhaps your frames were not made right, or were not V'd properly; but there are many friends of the Hoffman frame who have given their testimony on the other side. We should like to hear from Mr. Hoffman himself. Practical bee-keepers would not tolerate at the end of the top-bar any more space than just enough to allow easy handling.]

ONE OF NATURE'S BEE-HIVES IN CALIFORNIA.

I have a remnant from one of nature's bee-hives, brought in from the ranch of Mr. Louis Walker. Mr. W. had been burning mustard-stalks on a side hill near his house. After it had burned off, one of his helpers noticed honey and beeswax running over the ground; and upon investigation it was found to come from what was left of the shell of a pumpkin. Nearly three years ago Mr. W. had pumpkins on this side hill. Many of them were of large size. It appears that a gopher or squirrel had eaten a hole into this pumpkin, ate up the contents, leaving the shell, which dried in good shape for the bees to inhabit. Since that time the mustard had grown up and hidden all from view.

I have taken two immense swarms from badger-holes the past season. These are the few of the many odd places that swarms occupy in this section. M. H. MENDLESON.

Ventura, Cal., Jan. 25.

[The curious places that absconding swarms select as their future abiding-places, and the further fact that they seem to thrive, only proves what a wonderful bee-country California is. The old statement of Quinby or Gallup, that bees will do as well in a nail-keg as in the best constructed hive, seem to be verified in California.]

GOOD WINTERING.

My 110 colonies seem to be in fine condition after our cold snap. Every one was alive a day or two ago. I am wintering outdoors, packed in chaff. Nearly all of their stores are sugar syrup, with a little honey-dew. The bees spotted their hives very little after some three weeks of confinement. I sincerely wish I was as sure of having solved the wintering problem at this date as Ernest and his friends seem to be in the picture, page 60. S. A. UTLEY.

Mt. Washington, Mo., Jan. 28.

NOTES OF TRAVEL

FROM A. I. ROOT.

Jan. 2.—As we approached the line between Oregon and California we saw acres and acres of the most beautiful, thrifty-looking fruit-trees of various kinds, and the moss that has heretofore disfigured them to have mostly, if not quite, given way. What does it mean, such quantities of apples on the ground under the trees, red, yellow, and white, and the trees have been so full there is not room on the ground, without piling them on each other? I judge we have passed thousands of bushels, seemingly in good condition. At the depots, boys are offering most *beautiful* apples at a very low price, so I judge there must be a glut in the market in this locality.

We are on the mountain-tops, and the snow is over the tops of the fences. *Four* locomotives are pulling the train, and gangs of men are shoveling off the snow. In some places it is drifted up to the eaves of the house, and great channels are cut so as to get out and in. Not two hours ago it was as mild as May down in the valleys; but now we see great icicles, as large as a man's body, hanging from the eaves. At half-past 2 P. M. Mt. Shasta first came in sight from our elevation on the mountain-tops. It did not at first seem much different from nor much larger than many other peaks, only that it was, at least the upper part of it, of snowy whiteness. No speck of timber, vegetation, or rock, marred its waxy whiteness. Again, it has for an hour been almost constantly in sight, first on one side of the car and then on the other, as we wind about in our descent toward its foot. This distinguishes a high mountain from other peaks—its perpetual snow, and the fashion of looking just about the same, even while you travel to or from it, for hours. It now occurs to me I have said but little about the mountains as yet. When I first visited friend March's he told me that, right over his front gate, was a beautiful large mountain, to be seen only on a clear day. It seemed to me for several days that, if a mountain was there, I ought to see it; but not until a clear bright day did old Mt. Baker show itself. Then it loomed up in all its icy brightness until one was lost in awe and wonder. Friend M. says he does not believe any human being has ever reached the top, although one or more have lost their lives in the attempt. The trouble is, that it is always covered with ice, and in summer the sun melts caverns in this ice, with only a shell over the top, that often breaks through, precipitating the explorer into crevices from which he may never get out. From the same point of view we see two pretty smaller mountains. These are the Twin Sisters, and they are clear up in British America. All these are between 60 and 70 miles distant. From Portland we see Mt. Hood and Mt. St. Helen, when the day is clear. The former is a rugged peak, and over 11,000 feet high, and last July a party was sent to its summit to burn red lights on the eve of the Fourth. By starting several days ahead they made the ascent, and gave an exhibition of fire-works that could be seen for a hundred miles. St. Helen is not quite 10,000 feet, but it is the most symmetrical mountain, probably, in the world. At first sight it seemed to me that some butter-woman must have taken her paddle, and, by dextrous strokes, fashioned a thing of beauty. Mt. Shasta is one of the highest peaks in the United States, being 14,442 feet. The railroads are very accommodating in running the road almost up to the foot of the mountain. The drifting snow can be plainly seen with the naked eye, and the cloud of snow that is being constantly whirled over the summit must be something like a half or a quarter of a mile long. I took three kodak views of Shasta; but photography can not do a *real mountain* justice. One fails to recognize the distances and enormous height. A mountain two or three miles high might be estimated at less than a quarter as much.

Jan. 4, 1892. Yesterday was an eventful day to me. The deep snows on the mountain threw the train behind, so that I was compelled to travel on Sunday until nearly noon. While speaking of the deep snow I am reminded that a fellow-traveler explained how they clear the track. They have an immense machine, propelled by steam, that might be likened to a huge carpet-sweeper. It takes up the snow while it is yet light, just after it falls, and throws it over by the side of the track. When it has finished the job, the snow lies in a beautiful regular slope, exactly so far from the track, and this slope is at such an angle that it does not often slide or cave in.

In coming in to San Francisco we crossed two ferries. The first took the whole train, entire, without even dividing it; and I was told this ferryboat is the largest one in the world. The whole heavy train, locomotive and all, did not sink the great floating monster even one inch, so far as I could see. The second ferry that landed us in the city, by a system of gates and porters, took all on the train and nobody else. It was a beautiful morning, and the crowds all around me were dressed in their best, but nothing seemed to indicate that any one thought that it was *God's* holy day. I felt uneasy, and my conscience troubled me. As it neared church time I began to fear I should miss the morning service, and it seemed as if I could hardly stand it. I had selected from the various advertisments a temperance hotel, and so I pushed past all the hackmen, telling them I was going to stop at the O—— House. Finally one of them said, "Oh, yes! then I am your man exactly." As I got into his wretched vehicle I thought it strange a temperance institution should send out such a rig and man; and when he began threading the lowest part of the city I became uneasy; but he explained it by saying the direct route to their place was cut up by laying a cable car-track, and that they were temporarily obliged to go quite a piece around, and finally he dropped me before a low-lived whisky-shop. The office of the hotel was in said shop.

"My dear sir, you told me you belonged to the O—— House. How does this come?" and I pointed to the sign over the door.

"Oh! that is all right," he hastened to explain. "This house is owned by the same man that owns the O——. They are exactly alike." I looked at my watch, and saw I had just time to dress for church, if I went right at it and wasted no more time. So I explained I was in a hurry to get to church, and asked for a room. If it hadn't been Sunday I should have been tempted to use the Kodak to give our readers a view of that room. I was careful to hang my clothes on the hooks, while I hastily changed; and if I had dropped any article on the floor, it would have required brisk brushing to get it clean again, although the dirty woman we met at the door assured us the room was all in "nice order." When I asked to be directed to the nearest Congregational church the bloated-faced clerk went for somebody who knew about churches. Finally a policeman was found, and he said he knew of a new church, not far away, that he "rather *guessed*" was the sort I wanted. This policeman, by the way, could hardly talk English so as to be understood. My conscience begins to tell me now, however, that I have found fault enough. After all my fidgeting I was one of the first in that pretty new church. The janitor welcomed me with a handshake, found out where I was from, and introduced me to the different members as they came in, and finally to the good, kindly-looking pastor. Dear reader, if a stranger happens into your church are you *sure* he will get such a welcome? Why, it made me feel at home, and happy at once. How good their faces looked, contrasted with those of the crowd I had met on the ferry! We had an excellent sermon; but the best part of it was near the close, something like this.

"Dear brothers and sisters, I am extremely happy to tell you that my appeal a week ago brought a contribution that paid up every last cent of our debt, so we can start out this new year with our church and every thing about it paid for."

Many of the members spoke broken English, showing they were of different nationalities, and, in fact, the church was in a part of the town where it could not well be otherwise; but notwithstanding this they were clean and pure men and women, "washed in the blood of the Lamb," and made fit for the communion of saints. The contrast between them and the rough, blaspheming, and drinking crowd, was indeed wonderful. I was urged on all sides to stay to Sunday-school, and, in fact, by a perfect drove of children, chattering and prattling around the church door and steps, toward the close of the sermon, until the janitor had to look out several times and motion to them to keep still. I was happy and joyous then; but little did I dream of a new happiness just then right before me. Let us go back a little.

I have before mentioned that Mrs. Root is rather backward and diffident about going out in the world among people. When I started on this trip, our entreaties were all in vain to get her to come. It made her sick to travel, and she could not sleep nights; and, besides, she did not care for new countries and scenery as much as I did. So we reluctantly gave it up. By "we" I mean myself and the children. When I had a relapse of the fever, however, she said she *must* come to me; and, in fact, she could hardly wait until I could direct her how to come. Finally she wired me that she had started on Wednesday, the 30th of December. You may be sure that I did not forget her in my prayers during these four days. During the feverish, sleepless nights I had just passed, my mind was almost constantly drawn toward her. I dreamed of her nights, and while on the streets during the day. If any figure in the least resembled her, it set my heart to beating at once. Some of my younger readers may smile at this. All right. I am glad to have you smile, and I hope the older ones will smile. Yes; and *while* you smile, take that dear hand in yours that has worked for you so faithfully, and tell her that brother Root is not the *only* man who has a heart that beats young again as he sees the dear form or hears her footstep. More than thirty years ago I had a sort of boyish notion that I could not be happy without her. Since then I have seen her work untiringly in molding and fashioning the mind and soul of each little new comer that God sent into our household. I didn't know her thirty years ago, but I do know her know. While I was sick, and thousands of miles away from home, memory went over it all, step by step. As soon as she started I began to pray that she might not be made sick by so much travel. I prayed, and then worried for fear she *might* get sick and have to wire me or Ernest. I kept thinking she might get through on that eventful Sunday; but experienced travelers and railroad men told me it was *impossible* before Monday, and so I was going to all the churches and Sunday-schools, to pass the time until I might look for her.

Let me now go back again to that Fourth Congregational church in San Francisco. Instead of staying at Sunday-school I thought I would just go over to the place we had arranged for our meeting.

"Right there is Hill Street," said the conductor of the street-car; "and if you will walk up on this side you will soon come to No. 20."

I looked at the numbers, and walked along. Sure enough, here is No. 20, and somebody is just closing the door. As I rang the bell a gentleman opened the door, and, with a smile, said:

"And this is *Mr.* Root, I believe."

His next words seemed to stun me. I could not take in his meaning until he repeated them. He said:

"Your wife has just arrived."

"You surely do not mean she is here now, *in this house?*"

"Yes, I do; and she is right in that room."

I saw that the door was ajar. The fever had made me nervous. I pushed open the door, and there she stood—not used up and worn out with travel, but looking unusually well, happy, and just a trifle *saucy*. My prayers were *all* answered—yes, *more* than answered, and, as usual, I was *astonished*.

"O thou of little faith! *wherefore* didst thou doubt?"

The night before she started she had been awake a good deal; but after she really got on the way she slept soundly every night; yes, and she enjoyed the scenery on the way as she never enjoyed any thing before. As she did not leave the Pullman car for three days and four nights, the inmates got pretty well acquainted, and she says she never before met so many good and kind people in her life. I give all this in detail, for I feel sure that others may have the same mistaken notions in regard to travel at the present day. There are many advantages in having your wife with you in traveling. In fact, Mrs. Root has saved expense in many ways. When we came to Los Angeles a hotel-keeper wanted $14.00 for just a room, *without any meals*, for one week! Sue declared we would not stay there a single night; and she very soon found the pretty room, where I am writing now, for only $4.50 per week. It is nicely furnished (in fact, *better* than the one at the hotel), of good size, gas and other conveniences, near the business part of the city, and has a very pretty bay-window reaching out over the street. We can see up street or down, and street-cars are all around us, going for miles in any direction. We can get our meals at a choice of more than fifty restaurants; and there is scarcely an article of food to be had in the world that is not to be found here. There are so many nice dishes served for only five cents each, that, if one wishes to use economy, he can live very cheaply. Our meals usually cost us 30 or 40 cents for *both* of us; and a few days ago we got every thing we wanted, and the bill was only *twenty-five cents* for both. The grocers, bakers, and restaurants have such a great multitude of things, in the most convenient form, that, with the help of a little coal-oil stove, a good meal can be quickly prepared, for only a few cents. Many restaurants make a great specialty of fifteen-cent meals. You get almost any kind of meat or fish, including plenty of potatoes, bread and butter, and a large cup of good coffee, for the 15 cents. Fruits of all kinds known are in wonderful abundance, and are also very cheap. As neither of us carries a trunk, we can leave our baggage at the depot until we look up a furnished room to suit us, both in location and quality. Some of you may think it not much style to travel in this way. We don't care for style very much, and some of the finest people who travel do just this way. In fact, a lady in the Pullman car told me about it, and gave us the address of parties having nice furnished rooms to let.

As my sickness had thrown me back on my appointments we missed many points around San Francisco. In fact, we were obliged to start off Monday so as to be in time at the convention in Los Angeles. I mention this that the friends around San Francisco may not think we passed them by intentionally. Our kind friends, Mr. Bostwick, father and sons, did us very great service in showing us around the city. You should have seen Mrs. Root open her eyes as she saw the beautiful yards with their strange new forms of vegetation. Mr. Frank Bostwick seemed to be a privileged character in Chinatown, and he even went so far as to get us a pass into a Joss house during some great feast or event. We saw the idol, and the temple and worshipers. Their ceremonies and incantations, and the wonderful and varied apparatus, are wonderfully complicated. One would think, from their motions, that they were performing complicated problems and computations in astronomy or mathematics, while the real fact is there is no more sense in it than in the ravings and jargon of a maniac in some asylum. We saw Chinese, both women and children. If the latter could be educated, as we educate every other race, there would be some hope. Abandoning their queue means abandoning their religion, and there is no real hope for them until they do that. There are a few business men who have done that, and in Los Angeles we have a converted Chinese who is a minister of the gospel. I am sure it is all wrong to have so many men and almost *no women*, with any race of people. It seems to me there should be some law against it. I do not mean by this to tread on the toes of any of my bachelor friends.

We made one very interesting excursion to a beautiful park, where we saw seals climbing out of the ocean and clambering up on the rocks. These are not the fur-bearing seals, but are much like them. Their bark sounds like that from a lot of dogs, and one can hear them frolic half a mile away.

Between San Francisco and Los Angeles we did not see much of particular interest until we came to the Mojave (pronounced Mo-*hah*-vay) Desert. In many places vegetation is almost entirely lacking, and only the sandy gravel covers the boundless waste; and at noonday, even in the month of January, the glare and glitter of the sun's rays seemed oppressive. I am told that, in the summer time, it has been as hot as 116° in the shade. I began to look for the bones of animals that had perished, and soon found plenty of them, even in plain sight along the railroad track; and before long not only the bones were visible, but their partially decayed bodies. The air is so dry that no attempt is made to bury them, for they soon dry up, giving off little or no offensive smell.

Not far away is the far-famed Death Valley, where not only horses and cattle, but even human beings, have died in such numbers that skeletons are said to be in plain sight everywhere. In former times a superstition surrounded this place; but now travelers well provided for and well attended go through it safely. The heat is most intense; and as it lies low, there is very little air. This alone would be enough to induce fevers and delirium; but add to that the fact that the water found there is so alkaline, and charged with minerals, that it is almost poisonous, is it any wonder that animals and men become crazed and so insane they never find their way out? On the edges of the Mojave Desert are some very fine bee-ranches; and the great heat during the honey season is thought to assist in giving a large honey-flow when they do not get it in other localities. Mrs. Root was very anxious to see a mirage in the desert. Pretty soon I showed her a lake of water, with the sage brush and bushes reflected in it.

"Oh! but that *is* a lake!" she replied, almost as soon as I pointed it out. I told her to wait until we ran up nearer to it and she would see it disappear; but when we got where the lake should have been, she, "woman-like," was very much inclined to stick to her first position, and to declare that the railway had turned and gone away from it. I mention this to show you how *real* is a mirage.

At San Francisco there was plenty of rain; but when we neared the desert the weather was very dry, and it is still dry here at Los Angeles. We are having, in fact, the most beautiful summer weather here, right in the midst of January. Owing to my sickness I was obliged to give up many points I intended to visit, and, in fact, it was only by pushing ahead as fast as possible that we succeeded in getting here the day of the convention. I think I never attended a convention before where there was a better feeling among all present than at this one on the 6th and 7th of January. In fact, nothing came up during any of the sessions that savored in the least of any sort of discord. Many of the bee-keepers brought their wives, and Mrs. Root soon found herself among the best of friends. As soon as we were up and dressed on our first morning in Los Angeles I was in a great hurry to have Mrs. Root see the strange new vegetation of this semi-tropical land. It was a treat to see her look, and to hear her exclamations of wonder as we passed some of the fine dooryards. The palms and palmettos, perhaps, attracted the most attention. A beautiful park near the First Congregational church furnished no end of wonderful plants and trees. After the convention our good friend Woodberry took us on a drive through the mountain-passes from Glendale to Pasadena, on one route, and back again on another one. Mrs. Root asked me at night whether there were any more places in California so beautiful. A few days after, we visited Ventura, and with a livery team we drove 20 miles up into the Matilija (pronounced Mah-til-e-hah) Canyon. There is a particular spot near the hot springs that affected me so powerfully that I watched her anxiously to see whether it would be the same with her. When I had tried to tell her about it, away back in Ohio, she said she did not believe she cared for natural scenery as I did; but when we came to the point in question I was satisfied. Her expressions of wonder and awe became stronger and stronger, until human language became too weak to express the emotions of the soul. No one can describe a mountain. No picture can do it justice. There are points where the eye and feelings, and all previous judgment and experience, are compelled to confess their utter helplessness. You can't tell whether the road is going down or up, for you have actually seen the rivulet at the roadside so perverse as to run up hill. You at the same time confess you do not know whether the rocky cliff is near at hand or far away; neither do you know whether it is five hundred or a thousand feet high. The great rocks and cliffs appall you; and, to add to the illusion that it must be an enchanted land, the spring that bubbles forth at your feet is *too hot* to drink. We went a mile further up the rugged canyon on foot, and found an apiary of several hundred colonies. Its owner stays there only in the summer time; in fact, he uses it for a summer residence, and moves back into town when the honey season is over.

While friend Wilkin and I walked up to the apiary, the women-folks took a bath in the rude tent right in the bed of the creek. The sun was getting low and the air chilly, but I felt I could not go back until I too had taken a bath. I told them I could be ready to step into the carriage in ten or twelve minutes. The tent looked open, and I feared I should take cold; but when I closed the curtain partially I found it pretty warm, for the hot air poured out of every crack. How delicious and soothing the water seemed! It is so highly charged with chemicals that one can hardly keep his body under—it buoys him up like the salt water of the ocean. After I had got clear under, all but my nose, mouth, and eyes, I enjoyed it so much that I decided they would have to wait in the carriage five or six minutes more. So much clambering about and traveling had made my toes quite dirty. Now, don't be in a hurry to say that I am not neat in my habits, for I did it on purpose. I told Mrs. Root I wanted to test the cleansing properties of this water, without soap, and that she must let my feet stay so till we got to the hot springs. Well, I watched the chemicals at work, for the water is so clear that you can see in it for a foot or two, almost as well as through air. Sure enough, without a bit of rubbing, the dirt faded away right before my eyes, until my toes were as pink and clean as a baby's, and so it was with my whole body. I held my head under the spout, and rubbed it until the scalp was cleaner than any barber's shampoo ever made it. The horses and inmates of the carriage were impatient, and I hustled on my clothes, having been in the tent 18 minutes. I tried to give the proprietor his usual half-dollar; but he said my notice of the spring three years ago had made him many times my debtor; and when I talked to him about greenhouses and incubators with the surplus water, he told me water and the grounds were all at my service, free of cost, whenever I might choose to come and utilize it. I was prepared to hear Mrs. Root say many times that the mountain roads of the canyon were unsafe for even a *good* driver; and I knew, too, that she considered me a poor one, so I let the team "out" gradually; and as they wanted to go home, we went up and down with a rush, now within an inch of the sharp granite rocks on one side, and about as near a sharp precipice on the other, dodging boulders, and ever and anon plunging into the mountain-torrent as we crossed the stream from one side to the other. I do not know when I have enjoyed any thing more than that mountain-drive; and when we got home, just as the last glimpse of the twilight was fading, she whispered that she had more *faith* in her husband than she ever had before, "*as a driver!*" Had we taken the regular stage it would have cost $6.00, and we should have had to stay at the springs over night. With the livery we started after 10, took a couple of friends with us, stayed an hour and a half at the springs, and got back soon after 6 o'clock, and I had the fun of driving a spirited team forty miles. When we were married my wife and I took a steamboat-ride on the Ohio River, for a wedding-tour. Well, during all these thirty years we two have never since had a boat-ride together. When she saw the great ocean, and heard the roar of the waves, she naturally longed for a trip on it. By the way, she came across the Atlantic from "Merrie England" when she was eight years old.

GLEANINGS IN BEE CULTURE
Illustrated Semi-Monthly
36 Pages 7×10
$1.00 Per Year.

In the multitude of counselors there is safety.—PR. 11:14.

THE Vermont bee-keepers, in the State convention, report a good honey-yield for the last season. They were quite enthusiastic over it.

THE report of the N. A. B. K. A. is now published in pamphlet form. As usual, it is neatly and well bound. A noticeable feature about the report is the portrait engravings of the officers for 1891 and '92. It can be obtained of Thos. G. Newman & Son, Chicago, for 25c.

THERE seems to be a great deal of disagreement as to the rule that should be laid down for grading honey. But light is surely breaking in; and even should we be obliged to adopt a schedule that might be regarded as quite imperfect, it would manifestly be better than nothing.

IN spite of the cold snap we have been having throughout the country, reports are daily coming in to the effect that bees are wintering well. We feared that there might be some heavy losses in some quarters. Of course, the winter is not yet over; but the fact that bees are doing unusually well at the present time is encouraging.

THE foul-brood inspector for the province of Ontario, Canada, Mr. McEvoy, is doing some effective work. At the present rate, owing to the excellence of their law, and the effectiveness and promptness of their inspector, foul brood in the province will, at this rate, soon be a thing of the past. We hope the State of Nebraska, where the disease is said to be bad, will copy the example of the Canadians.

REPORTS are now in, and show that, of the queens sent to Australia and adjacent islands by mail, only about ten per cent failed to get through alive. A part of this loss, as one or two reports show, was due to an unusual douse of sea-water. G. M. Doolittle has likewise had remarkable success. By the way, he was the first one to send a queen successfully to Australia, and that was away back in 1884. We will shortly publish from him a couple of interesting articles on the subject.

C. P. DADANT says that sections open on three sides are the coming style. They can be so arranged that the tops are entirely closed—that is, the closed sides being on top. This may be some advantage to those bee-keepers who prefer to have their colonies fill only one tier of sections at a time. There is another class who like open-side sections, and this three-way style will accommodate them; and then, once more, these sections can be used like the ordinary, with only tops and bottoms open.

WE have received a number of letters from prominent bee-keepers all over the land, congratulating us on the candor and fairness of our reply to the report of the Ontario Bee-keepers' Association. This we naturally accept as an indorsement of every point we made on the part of the bee-keepers as a whole throughout the United States. Brother Newman, of the *American Bee Journal*, not only indorses our reply, but published it in full in his own journal, and then added some telling points that fully justify his action in the matter of incorporation.

WE have just been favored with a visit from Mr. Frank McNay, of Mauston, Juneau Co., Wis. He is a bee-keeper who manages successfully some 500 colonies. He has not occupied a very conspicuous position in the bee-journals of late, but he is one of the prominent and successful bee-keepers of his State. He runs almost entirely for extracted honey. In talking with him in regard to extractors, he seemed to favor the idea of the new Cowan reversible. We have promised to send him one, and no doubt he will report later in regard to its workings.

AT almost every convention there is more or less discussion in regard to indoor and outdoor wintering. One party will have entire success with one, and another will have failure with the other; and oftentimes some feeling is stirred up needlessly in the discussion. After having examined the matter very closely we have come to the conclusion that locality determines in a very great measure whether bees should be wintered outdoors or indoors. At the late convention at Grand Rapids it was interesting to observe what a difference there was in localities only a few miles apart, as to the coldness of the winter. Where the winters were very severe, cellar wintering seems to prevail. In fact, it was the only method that gave success. Where the winters were moderate the outdoor plan gave altogether the best results. In certain parts of York State, cellar wintering is the only plan that gives satisfactory results. In other parts the outdoor plan is preferred. We shall have to conclude, then, in view of these facts, that, in localities where the winter is so cold that the temperature is, for a good part of the time, down to or below zero, the indoor plan is the preferable one. But where bees have an opportunity for occasional flights, the outdoo plan will probably give the best results.

BARBARITY TO BEES.

ONE of the editorial writers in the New York *Tribune* seems to be greatly exercised over the fact that we have, on one or two occasions, pulled out 10,000 stings from as many bees, the stings being used to supply a large pharmacy concern who prepare a certain powerful and valuable medicine. Mr. W. T. Doty, in the *Orange County Farmer*, in commenting on this, says: "It remains for modern barbarism to devise the refinement of cruelty and nonsense in the use of apis mellifica." Neither of the above writers is attacking *us* any more than the whole medical fraternity of homeopathy. As to the utility of the medicine, that has nothing to do with us. They are both trying to stir up much ado about nothing, to get the people to hold up their hands in holy horror at such "cruelty" and "nonsense." As well, with equal consistency, they might decry the butchering of beef, dehorning of cattle, the gelding of male animals, bobbing of lambs' tails, or the cropping of bulldogs' ears. Gentlemen of the quill, there is a broad field here; you seem to entirely overlook the fact that the bee does not possess the same intricate and delicate nervous system, and therefore is by no means as susceptible to pain. If you had raised your voice against the dehorning of cattle, there might be some consistency about it. The ex-traction of stings was done almost instantaneously, and the bee was utterly crushed out of existence, and possible pain, in another instant. We do not see that we were inconsistent with our professions of the refined sense of humane treatment of our dumb animals of the present day. By the way, the writer for the *Tribune* does not sign his name, but hides in his attack under the editorial "we." If he scores anybody, let him score the junior editor. If a no worse charge is ever entered against him, he will be happy.

ARTIFICIAL (?) HONEY-COMB AT LAST.

On page 103 of our last issue we stated editorially that there were rumors abroad to the effect that another chap was about to place on the market artificial honey-comb filled with glucose; and now samples are out. This morning, as we came into the office, one of the clerks handed us a box and a letter, and added, with a laconic smile, "Here goes your thousand dollars as a reward for artificial honey-comb." As the information struck us from a pecuniary point of view, we were interested at once. Before we tell you about the comb, we present you the letter accompanying the mysterious box. Just read:

KANSAS CITY, Feb. 1, 1892.

A. I. Root.

Dear Sir: I send you this day per express, charges prepaid, sample of the artificial comb. One side is ready for the bees to fill and cap over, and the other side is filled with pure honey and capped over, so you see that the thing can be done, and is done. My idea is not so much to make artificial comb honey, as to supply the bee-keepers with artificial honey-comb so as to enable them to produce just six times more than they are now doing; as some say that it takes 7 lbs. of honey to produce 1 lb. of wax. This making combs is no experiment, but a fact, and they can be produced very cheap. This sample is some of the very first turned out; and by a little more work and pains it can be produced so near like what the bees make that you can not tell them apart. I expect to have my patent-papers in a few days; and if you wish to manufacture the comb under a royalty, I should be glad to figure with you, as I shall devote this month to several concerns—big ones like your own—making arrangements to manufacture under a royalty. This is a great invention, and a long-needed want soon supplied. Now the bee-keepers will rejoice, and the public will rejoice, because they can get all the honey they want; and no doubt I shall receive the reward by return mail, of a New York exchange for $1000, as published by you. I also send you a sample of brood comb. With best wishes I am

Yours truly,

—— T——

Of all the bungling attempts made to imitate artificial honey-comb, this is the worst. A piece of this imitation was inserted in an ordinary pound section. We pushed the comb out (or, rather, cake of wax with holes in it) and weighed it. By a little calculation we found that it would take about 8 ounces of wax to hold a pound of honey (a small fraction of an ounce of *natural* comb will hold a pound of honey); in other words, it would take 15 cents' worth of wax made into this imitation (?) to hold a pound of honey, and the very best comb honey wholesales at from 12 to 15 cents. But this 15 cents' worth of wax does not include the cost of manufacture and of royalties, and for these two items we must add at least 5 cents more. This makes 20 cents' worth of bogus honey-comb to hold a pound of honey; and yet Mr. T—— says it can be made very *cheap*. But, hold a minute! The sides of the cells, instead of being $\frac{1}{280}$ of an inch thick, as in the natural comb, are about $\frac{1}{16}$. We are bee-keeper enough to know that the bees would probably repudiate any such imitation. We have tested very much better samples of so-called artificial comb, but the bees utterly refused to recognize them. While the adjacent combs were filled with honey and brood, the artificial thing was left entirely untouched.

In the mysterious box was another sample of comb that contained honey. One side of the comb, we *suppose*, was intended to represent artificial capping. The side was perfectly flat, without corrugations or indentations, and resembled very closely the side of an unpolished marble slab more or less soiled with smoke and dirt. We showed it to a number of the employes, but they could hardly believe that any one meant that for capped comb honey.

The manufacturer of the adulterated product above is evidently not a very skilled bee-keeper, for he proposes to supply them with an article that "*will enable them to produce just six times more than they are now doing.*" Even if the comb could be made an exact duplicate of the natural article, this statement could not possibly be true.

After making due allowance for the fact that the sample was among the first made, we are not in the least afraid of losing our thousand dollars. Perhaps it would be well to state right here that our offer covered comb honey manufactured by appropriate machinery—that is, making the comb, filling it with glucose, and capping it over. But the candidate, in order to be eligible to the prize, must make his artificial stuff so perfect that it would be mistaken for the genuine article. If the sample sent is the acme of perfection, no doubt, if the senior editor were here, he would increase the offer to $2000; but we presume that, of course, Mr. T—— means the last as a joke.

It may appear to some that we are a little hard on Mr. T——; but we wish it clearly understood how far short his artificial comb comes of the genuine product. The general public would not rejoice. Just imagine the *pater familias* sitting down at the table, taking a bite of the stuff, and, for every ounce of honey that he swallows, spitting out half an ounce of *wax!* Bee-keepers, so far from rejoicing, would only laugh in ridicule at such a crude attempt. Does Mr. T—— suppose that consumers would eat this down as pure comb honey? and does he suppose that they would knowingly eat bogus comb honey?

We can assure our friend that there is no manufacturer of supplies who would for a moment consider the advisability of manufacturing such stuff. We would advise him to place samples of it in the hives, and see how quickly the *bees* will "doctor" them, and that will for ever convince him, if what we have said is not sufficient, that they are exceedingly fastidious as to the kind of honey-comb they have in the hive. They will accept the midrib, or embossed wax sheets, or, as we bee-keepers term it, *foundation*, and build it out into beautiful comb.

Foundation can be shipped, as it were, in the flat; whereas artificial honey-comb, or even natural combs, would have to go at a high rate of freight; and even if the artificial product could be manufactured so as to be acceptable to the bees, bee-keepers could not afford to use it, on account of freight rates. When it is remembered that foundation, in the height of the season, will be drawn out by the bees inside of 24 hours, it will be readily seen that bee-keepers have no need of foundation with full-depth walls, as it were. Another thing, even *if* the artificial comb could be made, it would have to be sold for *what it is*, or else be under the ban of the law. If our friend has not already secured a patent, we would suggest to him the wisdom of consulting two or three bee-keepers before he wastes his money. We would name, for instance, E. M. Hayhurst, of Kansas City.

SPECIAL NOTICES.

HOFFMAN-FRAME END-BARS.

We are having a number of inquiries for the prices of the Hoffman-frame end-bars alone. We furnish the frames complete in the flat at $1.70 per 100; $15.00 per 1000; the end-bars alone for 50c per 100; $4.50 per 1000 pieces; top-bars alone at 60c per 100; $5.00 per 1000.

CABBAGE-PLANTS, FEBRUARY, 1892.

We have a limited stock of extra nice cold-frame cabbage-plants that we are ready to ship now. Variety, Jersey Wakefield. See our seed catalogue for 1892. We can guarantee safe arrival at any post-office in the United States or Canada; but do not throw your plants away if most of the leaves appear yellow and the roots quite dry. Put the plants in a pail of water, which you should take into the field with you; take out one plant at a time; put it into *freshly worked* soil, pack the fine earth closely around the *roots*, not the stalk; draw a handful of soft earth around the plants, over the soil you packed down around the roots. Do not water unless very dry; do not hoe until after a rain or until the plant has commenced to send out new leaves, and you need lose scarcely a single plant out of the average one hundred sent you.

HURRAH FOR THE GRAY CARNIOLANS!

Bee-keepers, if you want a race of bees that will just pile in the honey, get the gray (only pure) Carniolans. For instance, here is a report of one of our apiaries of 50 colonies for the season of 1891: Honey crop, 7000 lbs. Yield of best colony, 230 lbs. Increase by natural swarming, 15 colonies. For further information write for circular and price list. F. A. LOCKHART & CO., Lake George, N. Y.
Please mention this paper. 5-6d

SUPPLIES. Langstroth Bee-hives, and every thing needed in the bee yard; 30-page catalogue free. **"BUSY BEES,"** a pamphlet telling how to manage them, 10 cents in stamps. *WALTER S. POUDER,* 5-12db
175 E. WALNUT ST., INDIANAPOLIS, IND.

APIARIST WANTED.—I want a man to run a small apiary. Time not spent with bees to be devoted to gardening and general chore work. Will pay $20.00 a month and board, or $35.00 a month without board, to the applicant who will furnish good references as to character, etc. Steady employment the year round will be given the right sort of man. **JAMES HORROCKS,**
5d **Hyde Park, Dutchess Co., N. Y.**

FOR SALE. Seventy-five colonies of bees in Simplicity hives. Price $4 a colony. Address WM. G. GRIFFITHS,
5d Chew, opp. Sharpneck St., Germantown, Pa.

HONEY COLUMN.

CITY MARKETS.

ALBANY. *Honey.* The market presents no new feature. We have received a number of small consignments since our last report; but the demand for comb honey continues very slow. Extracted is in better demand, and stock on the market small. We are entirely out of light, and not much dark on hand. Prices remain unchanged.

Feb. 20. CHAS. MCCULLOCH & CO.,
Albany, N. Y.

KANSAS CITY.—*Honey.*—Light demand; supply ample. White comb, 1-lb., 14@15; dark, 9@12. Extracted, white, 7½; dark, 5@6. *Beeswax*, light supply; demand good, at 23@26.

Feb. 20. CLEMONS, MASON & CO.,
Kansas City, Mo.

SAINT LOUIS. *Honey.* Market tame; little inquiry. Comb 10 to 12. Extracted, cans, 6½@7. Barrels, 4½@5½. *Beeswax*, prime, 26.

Feb. 20. D. G. TUTT GRO. CO.,
St. Louis, Mo.

PORTLAND. *Honey.* White comb honey, 1-lb., 15; 2-lb., 14; light amber, 1-lb., 14; 2-lb., 13; white extracted, 7; light amber, 6½. Stocks light all around. Local product about exhausted, and California practically supplying the market now. *Beeswax*, 25.

Feb. 12. LEVY, SPIEGL & CO.,
Portland, Or.

DETROIT.—*Honey.*—Comb honey is quoted at 12@14; the latter figure is obtainable only for the choicest. Extracted, 7@8. *Beeswax*, in fair demand at 26@27. M. H. HUNT,

Feb. 19. Bell Branch, Mich.

KANSAS CITY.—*Honey.* — Demand poor, with large supply of comb. We quote: Comb, 1-lb., fancy, 14@15; dark, 8@9. Extracted, white, 7; dark, 5@6. *Beeswax*, none on the market, light demand.

Feb. 20. HAMBLIN & BEARSS,
514 Walnut St., Kansas City, Mo.

CHICAGO.—*Honey.*—Our market is more active than it has been of late on comb honey; but prices are no higher. Best lines bring 15@16; dark and off grades, uncertain in price. Extracted selling freely, at 6@7@8, according to kind and quality.

R. A. BURNETT,
Feb. 19. 161 So. Water St., Chicago, Ill.

BOSTON.—*Honey.*—We quote: White comb honey, 1-lb., 14@15; no 2-lb. on hand. Extracted, 6@7. Market well supplied, demand fair.

Feb. 20. BLAKE & RIPLEY,
Boston, Mass.

CINCINNATI. *Honey.*—Trade is quiet. Choice comb honey brings 14@16 in a jobbing way. Extracted, 5@8 on arrival. *Beeswax*, demand good at 23@25 for good to choice yellow on arrival.

CHAS. F. MUTH,
Feb. 23. Cincinnati, Ohio.

FOR SALE.—California 2-lb. section comb honey at 12c per lb. Wis. and Mich. 1-lb. section candied comb honey at 11c per lb. If you want honey of any description, write us. S. T. FISH & CO.,
4-5-6d 189 So. Water St., Chicago, Ill.

Wants or Exchange Department.

WANTED.—A man capable of running an apiary of a hundred colonies for comb honey on shares, in one of the best localities, and has all modern fixtures.
E. L. WESTCOTT, Smith's Basin, Wash. Co. N. Y.

WANTED.—To trade a large lot of Heddon hives, nicely made and good as new; some with combs complete for honey, now or after crop of '92. Write for particulars. Address D. S. HALL,
2tfdb South Cabot, Vt.

WILL exchange lot 50 x 142 feet, well located, in Larned City, for high-grade bicycle, typewriter, Barnes foot-power machinery, or nursery stock.
A. H. DUFF, Larned, Kansas.

WANTED.—To exchange for Italian bees, complete set last edition American Cyclopedia, half Turkey, in perfect condition, 22 volumes, cost $5 a vol. Address CEDAR GROVE FARM, North Madison, Ind.

WANTED.—Position as apiarist. Have had considerable experience in raising queens and producing extracted honey. Have good habits, and am 48 years old. Am willing to work in any part of the U. S. N. F. CASE, Glensdale, Lewis Co., N. Y,

WANTED.—To exchange $35.00 saw-table, Stover's Ideal feed-mill and horse-power combined, and a lot of job type. Want supplies and honey.
2tfdb O. H. HYATT, Shenandoah, Page Co., Ia.

WANTED.—To exchange, red raspberry and blackberry plants for pure Italian queens, or eggs from pure poultry. E. R. MILLER,
4-5d Garden City, Cass Co., Mo.

WANTED.—For 1892, as learners, two young men, brisk, honest, and temperate. Can back instruction by 35 years of active experience in apiary.
4-5-6 S. I. FREEBORN, Richland Centre, Wis.

WANTED.—To exchange for strawberry-plants, raspberry or any small fruit, the Eclipse berry-box machines at $7.00; full description sent on application. Speak quick. A. M. MURRAY, Goshen, Ind.

WANTED.—To exchange apiary of 75 colonies, with every thing needed in the business, for land or other property or offers. Several valuable town lots in five railroad town; no better location for bees in Iowa or Wisconsin. Correspondence invited. 5-6d B. F. LITTLE, Brush Creek, Iowa.

WANTED.—To exchange a special Columbia bicycle, 48 in., Pope M'f'g Co., Mass., with bell and tool-bag; cost $125. Will trade for Italian bees. 5d
H. P. KETTERING, Greensburg, Pa.

WILL exchange P. Rock eggs and fowls, White Holland eggs and toms, Pekin duck and Toulouse geese eggs for bees, improved hives, nursery stock or offers. C. H. WALLACE, Homer, Ill. 5d

WANTED.—To exchange Graham's shorthand text-books for sections or foundation.
5d W. A. CAMPBELL, Sumach, Ga.

WANTED.—To exchange correspondence with parties living in Tenn., Ky., and Mo., who deal in thoroughbred sheep. H. C. DUTY, Walnut Hill. Ark.

WANTED.—A good energetic business man of experience, who can put in $1000 to $2000, to take hold of, and introduce a patent machine for making berry-boxes; a splendid chance. J. F. ADAMS.
5d Van Buren, Ark.

WANTED.—One or more pairs of ferrets. Will exchange choice Pekin ducks or pay cash. 5d
Address CHAS. MCCLAVE, New London, Ohio.

WANTED.—A position in an apiary. South preferred. Ample experience; references good.
5d WILMER W. MCNEIL, Wheelersburg, Ohio.

WANTED.—A Christian young man who has had some experience in care of bees, to work in garden and orchard. State experience, and wages wanted. J. H. EVANS, Lewiston, Idaho. 5-6d

WANTED.—A bee-keeper to work in our apiary. A young man who understands queen-rearing preferred. Address at once, giving references, expectations, etc. P. L. VIALLON M'F'G CO.,
Bayou Goula, La.

WANTED.—To exchange 80 acres of good timber land for bees. Land close to a railroad, to a good sawmill, and close to a good village. State what kind of a hive bees are in. BERT HANDY,
5-6d Richland Center, Wis.

WANTED.—Situation in an apiary, a single young man of four years experience. 4-5d
A. C. FUHRMAN, Pleasant Home, Ohio.

WANTED.—To exchange 60 straight brood-combs in L. frames at 12 cents each for supplies in flat. E. D. BARTON, East Hampton, Mid. Co., Ct.

WANTED.—A man to handle my bees the coming season. FILMORE COLE, Lima, O. 4tfdb

Free. 28-page **RESTRICTOR** book. How to avoid swarms, brace-combs, and losses in winter. How to get bees into sections in one hour; and rear queens in full colonies, etc., same old fixtures. C. W. DAYTON, Clinton, Wis.

My 654 Colonies of Italians

Are wintering well, and, as usual, I will sell a limited number of them to reduce stock to the required number. Each hive shipped to my customers will contain a full prosperous colony of Italian bees, with a last year's tested queen, on eight Hoffman frames of brood and honey. As my main object in handling bees is honey, we raise all our queens in full colonies from cells built under the swarming impulse, using the choicest and most profitable stock to breed from.

Safe arrival guaranteed in May and first half of June. For terms please address

3-8db **JULIUS HOFFMAN,**
CANAJOHARIE, N. Y.

☞In responding to this advertisement mention GLEANINGS.

Good Queens Cheap.

300 tested Italian queens, raised last season, for sale at $1; $10 per doz. A few hybrids at 25c each. They will be shipped about June 15th to 25th, or later if desired. Have order booked now and send money when you want them. My bees have been ***BRED FOR BUSINESS***, and these are bargains. Nuclei and full colonies at very low rates.

Send 25c for sample by mail of

THE UTILITY BEE-ESCAPE.

Thoroughly tested, practical and cheap. It cleans them out and they stay out. Any one can make it. Get a sample and make your own. 4tfdb

Vol. XX. MARCH 1, 1892. No. 5.

STRAY STRAWS

FROM DR. C. C. MILLER.

The grip has paid its compliments to both editors of the *B. B. J.*

How much does it cost you to raise a pound of honey? That's the question.

Clipping queens, in reply to a query in *A. B. J.*, showed 14 in favor and 9 against.

Carbolic-acid treatment for bee-paralysis is excellent, says J. B. Ramage in *A. B. J.*

Expensive hives are advised against in *B. B. J.* How would the Dovetailed suit?

I'm on the fence on the bounty question, looking for a good place to alight on the other side.

Full sheets of foundation in sections are preferred by 19 out of 23 repliers to queries in *A. B. J.*

Honey-dew is worked into vinegar by W. P. Odendahl (*A. B. J.*), and prime white vinegar it is making.

The windmill at Medina had a dejected look, and the greenhouse seemed very lonely without A. I.

A whisper comes that railroad rates to the convention at Washington next fall will be surprisingly low. Let's go.

Scratches in horses, a correspondent in *The Stockman* says, can be easily cured by bathing with thick sour buttermilk.

"Honey creams" and "Honey Scotch" seem to be two items of confectionery on the British market that are made from genuine honey.

Cost of producing honey was discussed at the Colorado State Convention. Porter said 4c per lb.; Aikin and Rauchfuss 8, and Adams 10½.

E. Bartrum, D. D., in *B. B. J.*, warns against low hives, on account of backache from stooping. Sit down, doctor, sit down, and take it comfortably.

Graybeards were in the majority at the Ohio State Bee-keepers' Convention. Never saw so large a proportion in a gathering of bee-keepers.

The *C. B. J.* thinks the Ontario convention would have been better if there had been more bee-talk in it. Bee-talk is a good thing in a bee convention.

Foundation-mills making 4½ cells to the inch, they told me at Medina, were ordered—nine of them, I think—from Russia. I wonder if Russian "swear words" won't be overtaxed next fall.

The British government makes an appropriation through which county councils provide lectures and technical instruction in bee-keeping. Good for the Britishers!

The *White Mountain Apiarist* suggests that "some bee-keeper living in or near Chicago open a boarding-house for bee-keepers during the World's Fair in 1893."

May is the sunniest month bee-keepers have in England, and yet in that month the sun does not shine half the time it is above the horizon. We might swap them some of our "scorchers."

Editor Newman looks a good deal as if a train of cars had run over him. But the grip hasn't taken all the grit out of him. Just say "adulteration" to him, and you'll find he's not dead yet.

Prof. J. L. Budd recommends sowing orchards with Japan buckwheat about the first of July. Makes larger, cleaner, healthier trees than the usual cultivation, and the fruit more abundant and uniform in size.

An almanac is very handy in a family to keep track of the days of the month; but if you subscribe for the "old reliable" *American Bee Journal* it will keep you straight as to the day of the week. Never misses.

Don't tell what per cent you lost in wintering till your bees are past all danger of spring dwindling. I can winter 100 per cent every winter by taking out of the cellar in January, but I wouldn't have many left in June.

I don't know what those Frenchmen are hinting at on page 116. I know the Dadants have "no swarming to speak of," and I think if I should run for extracted honey I wouldn't have a tithe of the trouble with swarming I do with comb honey.

When a man gets up in a convention and begins, "I am only a learner, but I wanted to ask the best way to do" so and so, you may look out for a plan of his own that he'll fight for as away ahead of any other, and nine times out of ten it's either old or worthless.

The right temperature for cellars, I've always said, each one must find out for himself, as cellars differ so. I don't know of any better way yet; but if they keep on fooling with wet and dry bulb thermometers they may yet give us some rule of universal application.

Have you ordered your supplies for the season yet? You can tell just about as well now as any time how many sections you'll want, unless you wait till the bees are storing, and you may have trouble in getting them in time then. Better be in time, and have enough too. Yes, be sure to have a little *more* than you want, for there's no harm in having something left over for the next season.

Hutchinson has a new picture of me, taken in the enjoyment of good health. His pictures are all right now, and are a very pleasant feature of his journal. As I look at the one of B. Taylor, it seems as if he were just about to make some droll remark, ending up with his inimitable drawl.

Getting pollen out of combs. Here's a good way from Doolittle in *Stockman*. Shake together 2 qts. boiling water and 1 lb. honey. Put in sprinkling-pot and sprinkle combs. Leave in warm room till fermentation throws out most of the pollen. Rinse with warm water, shake off water, and put in hives at night, one comb in each strong colony.

An average crop of honey—what is it? It seems as though some one might find out what has been the average per colony, the country over, for the last ten years. But each one can find out his own average for himself; and I don't believe half the bee-keepers who say "I've had an average crop" have any definite idea of what they are talking about.

Henderson, referring to the editorial remark about "good sleighing," on page 66, wants to know whether sleighing hurts the honey-plants in embryo, or whether the matter is with the comb, or the secretion of wax. All wrong, Bro. H. It's the weight of the snow that holds the clover down, and makes it so dark it can't see to throw up blossoms to be killed right in the middle of winter.

G. E. Tufts, Spring Bluff, Wis., says for several winters he has, with very little loss, wintered bees much as I described in Gleanings. He uses chaff instead of straw, which he thinks better for their 40° below zero; lets the hives drift under out of sight, and remain so all winter. He doesn't take any special pains about moving, and bees don't fight; and if they do mix and equalize, what harm?

Clipping queens, the *B. B. J.* thinks, is a cruel habit, and one which is dying out. Is it any more cruel than many other things we do for our own benefit with creatures under our control? Of the hundreds of queens I have clipped, I never saw one show any sign of suffering, nor did I ever know it to check laying in the least. As to the habit dying out, what proof have you, dear *B. B. J.?*

I wish you could all see that specimen of artificial honey-comb and *comb honey* they have at Medina. The latter, except as to shape, looks a good deal like a doughnut with sugar sifted over it, only not so inviting. The empty comb looks as though some little girls had formed cups of wax over the end of a slate pencil and set them together. But language fails to describe it. You just ought to see it!

I got an oil-stove. Delighted with it!—carried it into any room, heat it up so easily for almost nothing. Nice thing for bee-cellar. I left the oil-stove in a closed bedroom three hours, then went in with lamp. The blaze of the lamp dropped right down. I then took the lamp out into the hall, and the blaze came up bright. I took the lamp back into the room—blaze dropped; took oil-stove back to hardware store. No more oil-stove for me.

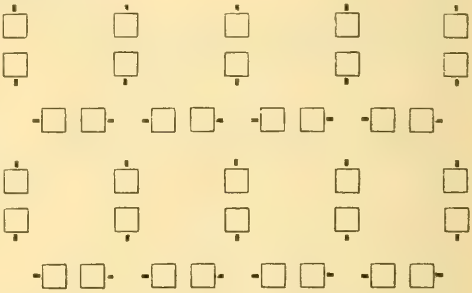
There's much in getting the knack of a thing. I saw Ernest work a Daisy foundation-fastener. I was delighted with its working. Then I tried it. The thing balked. Then it went all right for Ernest every time, but I couldn't make it go. I don't think I'm stupid. I'm only bashful. If he hadn't been watching me I could have made the thing go. I'm going to get one of my own, and learn. I don't propose to be outdone by a young upstart like Ernest.

JULIUS HOFFMAN, AND HIS METHODS IN THE APIARY.

HIS SHORT CUTS, AND HOW HE MAKES BEES PAY.

During the long evenings that have intervened since we described Mr. Hoffman, his home, his cellars, his ideas, and modes of wintering bees, we trust you have grasped the salient points and can apply them to your own practice. True, if you live in a mild climate, or use a very different hive, you may fail to get much benefit from the experience of Mr. H. If so, this article may prove more interesting.

After much study and observation Mr. H. adopts the following arrangement of hives in his apiaries.



As the bees fly from so many directions, there is much less mixing up than when all face the same way. By reference to the engraving in Gleanings for Feb. 1, page 90, you see the covers are flat; hence, by setting the hives in pairs one makes a convenient stand for the smoker, etc., while the other is being operated upon.

The stand upon which each hive rests is simply two pieces of 2 x 4 scantling. To one end of each a board 4 inches wide is nailed. Over the edge of this, and extending over the two sills, a board about five inches wide is fastened. This is the alighting-board; and when the ground is smooth and level, bees can not get under the hive. A glance at the engraving referred to will make all plain.

By way of parenthesis, we told Mr. Hoffman, and state here for the benefit of the reader, that, if all these pieces are well soaked with crude petroleum before being nailed together, they will last more than twice as long as though simply painted or left unprotected. Crude petroleum costs very little; and when its merits as a wood-preserver are generally known it will be largely used.

Mr. Hoffman's hive is 14 inches deep, 16¼ long, and 11½ wide, made of ⅞ pine. A rabbet, about ¼ inch deep and $\frac{5}{16}$ wide, is cut into the long pieces, hence the frames are even with the top, and extend across the hive. The bottom is nailed on, making a strong box not easily racked out of shape. About ¾ of an inch from the upper edge a rim of ⅞ strips is nailed around. This supports the cover, the upper story when extracting, or the surplus box honey-case. Half the thickness of the upper edge of this rim is beveled down to prevent rain from working in.

We said, "Mr. Hoffman, why don't you rabbet the covers, and dispense with this rim, and cut handles into the hives to carry them by?"

He replied, "That would retard in handling and carrying the hives, and would cause loss of time in the busy season."

Mr. H. stated that, for some years, his chief study is to shorten methods and dispense with loose pieces, and reduce the manipulation to a science; i. e., depend upon certain operations to return uniformly the same results.

The openings for the bees are three 1½-inch holes, facing the hive, one in the left end, two in front (see the engraving on page 90).

The lower one in front is only ¼ inch from the bottom-board. Mr. Hoffman has used tin slides, iron slides, and wooden slides, to cover bee-hive entrances, but none of them ever pleased him. At last he solved the problem. A strip about five inches long, 2 inches wide, and ⅜ inch thick, has a small hole in the center. Near one end a 1½-inch hole is bored, and enough of the thickness cut off to nail on a block of wire cloth. This strip is then ready to fasten, by a screw to the hive, wire side down. One way it ventilates; the other it closes the hive or graduates the size of the entrance to suit the operator. The first hive on the left shows an oblong entrance at the bottom; but this hive was made by another, and was taken on a debt.

The followers used at the sides of the frames are half-inch stuff. A strip is nailed to the bottom edge and one at the top. The latter rests upon the rabbets as do the frames. These followers reach to within about ⅝ inch of the bottom, and are ⅜ inch narrow at both sides. A thin saw-kerf is cut into both edges at the sides for five or six inches from the top end. Into each of these a piece of thin rubber packing is fastened extending out ⅜ inch. Now the followers are close-fitting at the sides for four or five inches only.

When colonies are to be drawn to out-apiaries, or *vice versa*, the operation is very rapid. The bottoms are fast; the frames are propolized enough to hold in a spring wagon; the wire cloth ends of the buttons or circular slides are quickly set in position; a piece of sacking, a trifle larger than the hive, is laid on, and the cap pressed down over it. Drive up the wagon and set the hives on. Mr. Hoffman's man can and has hitched the team, and prepared, loaded, and roped, 28 hives in 30 minutes, ready to drive off. Who can equal this? The ventilator in the end of the hive now answers a splendid purpose. The bees have full range, and some cluster in the open space where plenty of air is supplied. The cap and rim on the hive make it impossible to cut off a supply of air between the hives while on the wagon. The hole in the end of the hive also makes it convenient to rear an extra queen or divide the colony early, thus economizing warmth. A division-board for this purpose is made exactly like the followers, except that the rubber strips extend around both sides and the bottom. The bees are thus effectually separated. When a nucleus is cut off from the main colony, the hive is turned partially around, so that the stream of bees coming from the field is divided. A little observation will show whether this is properly accomplished.

The cap (or cover) of the hive is simply a rim two or three inches deep, covered with boards, over which a sheet of iron is placed, the edges of which extend down over, and are tacked to the sides of the cap.

Extracted surplus honey is obtained as follows: One follower is removed, and ten frames occupy the hive. The space between the follower left in and the end of the hive is ½ or ⅝ inch. Over the frames and edge of the follower a sheet of heavy enamel cloth is placed. On this a bottomless hive is put. Frames of comb for surplus are placed in the upper hive, beginning at the end near the follower. The only access the bees have is below and at the sides of the follower. The queen seldom gets into this upper story, and the bees work up very satisfactorily. Every eight or nine days, when honey is coming, these hives are overhauled. The top story is removed. The three first frames are examined. If the hives are well filled with bees, and these frames contain brood, one, two, or three are removed, the bees partially shaken off and replaced with empty combs. All frames containing honey are taken from the upper story, and empty combs substituted. These are put in racks, and go home to be extracted. When eight frames of brood are ready they are set into an empty hive. A strong colony is moved a short distance, and this hive placed so that part of the bees go into it. The operation is repeated throughout the yard. None of the frames in the lower hive are moved, except the first three.

Mr. H. says if they are handled, bees are more apt to swarm. This was new to us.

A strong colony containing a select queen is made queenless. The combs are examined, to be sure that no capped queen-cells are present. In eight or nine days the process described above is repeated, except that the eight frames of brood in empty hive are generally placed on the stands occupied by the new colonies made eight or nine days before. This is done to weaken them, so that a hatching queen shall not be molested. The colonies made on the previous occasion are overhauled, and all queen-cells destroyed. Before the work of the day is over, a lot of cells are cut from the hive of choice brood made queenless at the former visit, and one is set between two combs of each of the queenless hives. If necessary the frames are separated a little, and the cells pressed in a trifle. At the next visit, if the cells appear to have hatched, no examination is then made. About a dozen thin twigs from apple or similar trees are securely tied together. With this the bees are removed from the combs. No wing or brush is used.

If the queen ever gets into the upper (or surplus) story she is shaken down in front of the hive, and the brood treated like the rest.

Mr. Hoffman said, "I wonder how many of the readers of GLEANINGS remember to use grass in the entrances to prevent robbing." We replied, "How many of them use similar entrances, and can successfully employ grass for that purpose?" The process is as follows:

Before a hive is opened, a handful of grass is stuffed loosely into the entrance. This obstructs the bees that belong in the hive and increases the guard; at the same time, the robbers are not able to dart in unchallenged. No attention is paid to the grass. It gradually dries and shrinks, and the bees carry it away.

We said, "Mr. Hoffman, if you hadn't a hive in the world, and could start all over, what size frame would you adopt?" He answered, "I would make no change unless I made the frames one inch shallower. This I would do, if at all, only because 14-inch boards are not easily obtained, and are rather expensive."

Mr. Hoffman's family consist of four girls and two boys. His good sense is demonstrated in that, when the children are young, they are taught only German. As they grow older, English comes as a matter of necessity. The love of music is inborn. The youngest, a girl only two years old, unconsciously hummed a popular air, to our great satisfaction.

Mr. H. says his boys do not "take to bees," hence he will give them practical lessons in organ-building. A dozen are to be manufactured, and the boys are to assist.

Modesty prevents Mr. H. from stating the facts; but, aside from his management of 600 or 800 colonies, he does a good deal of other work, and has a revenue of several hundred a year, exclusive of the income from his bees.

Canajoharie, N. Y. J. H. NELLIS.

You have given many valuable points, friend N., in regard to our modest friend Mr. Hoffman and his methods of work in the apiary. For the last fifteen years he has been working quietly in this way, while the outside world knew little or nothing of him, much less that he had a brood-frame that now seems to be taking the apiarian world by storm.

When we visited Mr. Hoffman we failed to observe that he had his hives arranged in pairs; yet many intelligent bee-keepers are beginning to think it economy to put hives either in pairs or groups. In Mr. Hoffman's method of arranging hives, the entrances all point toward each other; and the bees, as it were, in their flight are focused toward one spot; and that spot is in the center of a group of four hives. We have never tried exactly this arrangement, but something similar to it. At present we rather prefer the plan we advocated on page 922, Dec. 1, and 959, Dec. 15, of having the bees occupy one alleyway for their flight, while the other would be comparatively free for the apiarist.

Mr. Hoffman is a good deal like Dr. Miller—he wants a good substantial cleat with which to pick up his hive. We can readily understand how one who has become thoroughly accustomed to the cleats would not readily be satisfied with handholes made with a wabbling saw. We who have always been accustomed to handholes find no particular inconvenience in lifting hives by them to the wagon, or for any other general handling.

When we visited Mr. Hoffman we were particularly interested in his kind of entrances. This, together with several other things we saw about the place, convinced us that he was pre-eminently a bee-keeper who used "short cuts." These entrance-holes can be very quickly closed; and they have, besides, certain other advantages. If bee-keepers could be content to use hives with tight bottoms, perhaps these entrances would be preferable to a long slot; but there are advantages in long narrow entrances not possessed by 1¼-inch holes. The former, the mice can not get through; and where frames are shallow, like the Langstroth, the long narrow entrance is better, because it gives more alighting room for the bees when coming in laden with honey.

On page 737, Sept. 15th issue, last year's volume, you will remember that two of us prepared and loaded 57 hives in an hour and a half. At the time, we made this statement to prove that bees could be handled on Hoffman frames rapidly, and that hives containing such frames could be quickly loaded on to the wagon for moving. We thought we were doing pretty big things, and so did our friend A. N. Draper, of Upper Alton, Ill. On page 463 of the *American Bee Journal*, Oct. 8, he challenged the statement. But it seems that Mr. Hoffman's man prepared and loaded 28 in 30 minutes alone, and this would be 56 hives in one hour. We two loaded only 57 in an hour and a half. From this it would appear that Mr. Hoffman's man did the work in about two-thirds the time that *two* of us did. According to the way in which we worked, one of us would have loaded 57 hives in three hours; but Mr. Hoffman's man would have loaded 56 hives in one hour. This will be a poser for friend Draper. If our feat seemed difficult of accomplishment, what must he say of the apiarist of Canajoharie? After all, the credit is not due to him, but to his employer, Mr. Julius Hoffman. And this shows quite conclusively how Mr. H., with his appliances, manages his apiaries with the minimum of labor and expense, and how he would make money when others would lose.

There are two other points to which we should call attention: That handling frames or disturbing the brood-nest is liable to increase the desire for swarming. If any of our readers have made observations on this point we should be glad to hear from them.

Another point is the use of grass in stopping robbing. Dr. Miller has used the same scheme, especially when working with out-apiaries. The entrances may be plugged tightly with grass, and, in a couple of hours after the robbers have given up and quit their nonsense, the grass will have wilted, and opened the entrances automatically, although the apiarist may be miles away.]

THE ALBANY GRADING.

MR. ELWOOD EXPLAINS IT.

In a recent issue of Gleanings the editor calls attention to the fact that, in the markings for the Italian bee, the numbers do not foot up an even hundred. As I remember, the missing ten should be added to wintering, making it twenty-five, and the whole scale substantially the same as Mr. Knickerbocker put it in his essay. The only change made was five taken from color and added to honey-gathering and comb-building qualities. In future it may be thought best to divide the last-mentioned points and give each one a separate marking. Bee-keepers do not object to handsome bees, but they do object to having this accomplished by in-and-in breeding to the exclusion of the far more important qualities. The original report was hurriedly corrected in pencil; and although Mr. Hutchinson prides himself on being skillful in deciphering hieroglyphics, it is perhaps not strange that he failed on this. Probably for the same reason the report on grading honey was not given correctly. The report says, "Honey shall be graded in two grades," and then proceeds to name four regular grades. It should read, "White honey shall be graded in two grades." The description of the third grade is also defective. The complete report should read as follows:

White honey shall be graded in two grades:

The first to be known in the trade as "fancy," or "fancy white," and to be marked "A." It shall be composed of well-filled sections of light-colored honeys. One face of each section shall be perfect in appearance, fully sealed, except the line of cells touching the wood. The other side of the section shall either be perfect in color and sealing, or nearly so.

The second grade shall be known in the trade as "fair to good white," and be marked "C," and shall be packed to meet the requirements of those desiring a good honey, but who care little for outside appearance. It shall be composed of honey thrown out of the first grade, irregular and travel-stained combs, sections not perfectly filled, but yet having but little unsealed honey.

The third grade shall be known as "mixed honey," and shall be composed of white honey chiefly, mixed with inferior honey, including buckwheat and fall flowers, and shall be marked "M." We advise that combs so badly stained as to have the color of saffron be thrown into this grade.

Buckwheat honey shall be packed by itself and be marked "B."

Those bee-keepers sending to market boxes known as "pieces" shall put upon them a private mark of their own. This should also apply to honey-dew, and any other kind not falling into regular grades.

This report was made with the knowledge that bee-keepers usually stencil their honey with their full address, thus giving the State and locality in which the honey is produced, which is important in judging of quality. While the first and second grades are composed of light-colored honeys it is, of course, expected that the lightest colored will go into the first grade, and the darkest of the light honeys into the second. Great care should be taken that mixed honeys, or honeys of too dark a shade, be not put into the "C" grade. It is impossible to express on paper the slight variation in shade of honey that will often throw it from one grade to another. Grading honey is one of the most difficult tasks the bee-keeper has to do; and no one with much experience is looking for short, explicit rules that will cover all cases. It is something that can not be done by lamplight, and very seldom, indeed, by proxy.

The committee thought best to use the letter "A" on first grade. "A" has been used for many years (fifteen) for the first grade; and as it is the first letter of the alphabet, nothing can go ahead of it. Should some ambitious individual use it double, it would express less rather than more. For the second grade, "C," the old mark for clover or white honey, was chosen rather than "B," which has always been the mark for buckwheat honey. To have changed these letters would have caused confusion; and, besides, the lettering would have been in nowise descriptive. Then, again, if the letters had been taken in regular alphabetical order (A, B, C, D), it would imply that the quality followed in the same order, making it little less objectionable than the numerals 1, 2, 3, 4. It would also place buckwheat honey third in quality, whereas it stands first in quality with many consumers, and in some markets it is also first in demand. By the system of independent lettering, each grade stands on its own merit for quality. Any attempt to grade or pack buckwheat honey with other dark honeys, as suggested by Mr. Frazier, in the last issue of GLEANINGS, will prove a complete failure. Those who buy buckwheat honey buy it because they like its flavor. They want nothing else, and it should be marked so that it may be known. Mr. Frazier makes nine qualities, which is double the number necessary, and twice as many as dealers will accept. His classification, however, is a wonderful improvement over the Chicago grading, which is worthless. It is worse than worthless, for it supplants better methods and practices. It was not severely criticised at Albany, for it was felt to be a piece of bungling work that, the less said about, the better. The recent attempt to revive many of its objectionable features calls for a few remarks.

It will not do to throw out a section from the "fancy" grade because it is not firmly attached to the bottom. Some of the finest honey ever marketed is of that kind, and all the trouble it causes is in packing, when it should be turned upside down. Then, again, nearly all sections show travel or propolis stains, even after careful scraping, and it will not do to throw these out for the very slight stains remaining. Not only are such thrown out of the first grade, but out of the second as well. It will not do at all to grade honey by the color of the box, and say nothing about the color of the honey. By the modern system of marketing, in which orders are given to canvassing grocers, and goods delivered, honey-boxes are not usually seen by the consumer, and the honey itself not seen until upon the table. This fact was taken into consideration when the Albany committee decided that a box of honey, very slightly imperfect on one side, might be graded as "fancy." The best side always goes up on the table, when in appearance and other qualities it is strictly "fancy." In the first Chicago grade all cells are to be sealed, including the line of cells touching the wood. Now, a section is just as fancy—just as good in every way—if these cells are not sealed. The honey also carries fully as well, for any straining of the box will crack the sealing of this line of cells, and cause it to leak badly. When these cells are unsealed the bees usually remove the honey before the section is removed from the hive. In their third grade go such sections as are less than three-fourths filled with honey, and these may be partly or wholly unsealed at that. Such sections ought to be left at home, as the general marketing of these can not fail to injure the market. When they are shipped, let the producer place on them his private mark, and never *forget* to add his full name and residence. The same may be said of sections containing chunks of bee-bread. The man who buys one of these last will not want any more honey for some time.

Three grades of each kind of honey is more than the market will bear. White clover, alsike, alfalfa, basswood, poplar, sourwood, locust, blue thistle, white sage, blue sage, sumac, buckwheat, goldenrod, and a dozen other kinds multiplied by three, would strike terror to the heart of the dealer. Had Mr. Baldridge's complete draft been adopted it would have reduced the qualities to ten or twelve, and, in justice to Mr. B., ought to have been done, so as to have made sense of the remainder.

Some of our committee rather favored another grade of white honey; but the honey-merchants present vigorously protested against having so many grades, as it would only bring confusion. It was thought by the majority that light honey would bring more in two grades. If in three grades the first (a small quantity) would bring more; but the second (a much larger quantity) would bring less, as it would not be as nice. Even if so small a quantity were taken from it as to make no perceptible difference in quality, the knowledge that this was not the best would weaken prices. The third (or mixed) grade will take all honey not light enough to go into the second grade, except buckwheat, which, as before stated, must be packed by itself.

I notice that our secretary (W. Z. H.) says in the report, that "these rules were not the sentiment of the majority of the members of the convention." I had supposed the duties of the secretary were clerical, and that any opinions he wished to have appear in the printed report would first have to be pronounced before the convention. It is hardly fair that a statement of this kind should appear in our annual report, as the facts in the case will not warrant the assertion. A large part of the honey sent to eastern markets, particularly to New York, is graded by substantially these same rules, with somewhat different letterings, and they are the result of many years' experience in marketing honey. The uniform satisfaction given by this system of grading does not make it perfect, but there is no doubt that, after discussion in a full convention, made up so largely of eastern men, the report would have been adopted with no radical change.

Starkville, N. Y. P. H. ELWOOD.

To be continued.

[Perhaps we shall have to own up that we here at the Home of the Honey-bees took the original drafts of the committee on grading the Italian bee, and sent copies of the same to the editors of the *Bee-keepers' Review* and *American Bee Journal*, and therefore we shall have to shoulder the inaccuracies of the report on grading and accept the correction.

Mr. Elwood's article throws much light upon the Albany grading; and as he explains it we have but little fault to find with it. Unlike some of the other gradings, it is not based upon theory, but upon fifteen years' experience, of the largest bee-keepers in the world, together with that of the largest honey-merchants. The fact that it is accepted in the East, and been practically in vogue all these fifteen years, is much in its favor. We feel compelled to acknowledge that any system of grading that calls for a large variety of classes will fail of adoption. It must be something simple and practical.

Buckwheat honey is not called an inferior article in the East. As we have before stated, we reiterate again—there are thousands of consumers who consider this the *only* nice honey. Our travels and sojourns in the East among the consumers and bee-keepers, and our conversations with boarders at hotels, prove this beyond question. It is a mistake to place other dark honeys along with buckwheat; and any attempt to do this will be rejected by bee-keepers, honey-merchants, and consumers in the East.

In the West there are several fine grades of honey, such as heart's-ease and fireweed (or epilobium) that have a cream color of capping, but are regarded as first-class honey. All fine honeys of the East are either white or the color of buckwheat; and considering these two differences in localities, it begins to seem to us now that it would be impossible to adopt one system of grading that would be accepted by the bee-keepers of both East and West, and therefore *two* systems will be the natural result. There is nothing impracticable in this; for when bee-keepers wish to send honey to a distant market, they can say that their honey is graded either by the Eastern or Western schedule and the buyer can consult either schedule, to see what he is buying, or about to buy, and be governed accordingly. We know that railroads make a distinction as to locality, and they have therefore what they call their Eastern and Western classification in freight, and why not two schedules for honey?

As this is to be a sort of symposium on grading we have thought best to reprint the schedule of grading recommended by J. A. Green, as it is referred to several times by Dr. Miller in the article immediately following.]

EXTRA SELECT.

Light-colored honey, of good flavor; combs straight, well built out, of even thickness, and nearly uniform weight, attached to the section on all sides; all cells sealed, with white cappings, and with both comb and sections unsoiled by travel-stain or otherwise.

"A" GRADE.

Light-colored honey, of good flavor; combs straight and well built out, with cappings white, or but slightly amber-colored; one face of each comb perfect in appearance, fully sealed, except the line of cells touching the wood. The other side shall be perfect in color and sealing, or nearly so, and section not badly soiled.

"C" GRADE.

Honey of good quality. In this grade shall be placed all irregular combs, or those containing pollen, and all in which the capping is dark or considerably soiled. Sections must be nearly filled, with few or no unsealed cells.

"M" GRADE.

In this grade shall be placed all honey of inferior quality, all combs containing much pollen, or badly travel-stained, or otherwise objectionable. Sections must be at least three-fourths full, with one side well sealed.

GRADING HONEY.

DR. MILLER DISCUSSES THE DIFFERENT GRADES.

When the subject of grading honey came up at Chicago I felt we had struck a topic of live interest; and although the system there adopted did not seem to me one likely to go into general use, still it was a start; and, a start once made, the matter was not likely to rest until it grew into what was good and practicable, if such a conclusion is possible; for it can not well be denied that there are real difficulties to overcome on account of the great diversity in honey in different parts of the country. In proof of the difficulty of arriving at any system that shall be satisfactory to all, it is only necessary to recall the action at Chicago; and, indeed, I think, from the report, that much the same thing was repeated at Albany. At Chicago an intelligent and honest committee utterly failed to come to any satisfactory agreement, although continued from session to session. Then in general session an agreement was reached only by each one being willing to yield much, with the feeling that any thing was better than not to make a start at all.

I suspect that any thing like a satisfactory system will be reached, if reached at all, only by a great deal of discussion; and it will be well that such discussion go on now without waiting for any convention to meet next fall or winter. So far, I think good has been done. We have now the Chicago system, the Albany system, and that of J. A. Green, each one improving, at least in some respects, on what had gone before.

Now, I suppose you will be asking me what my system is. Frankly, I haven't any. Dr. Mason reported at Chicago that no two of the committee could agree. I believe that it was admitted that one member of the committee had no difficulty in coming to an agreement but for the stubbornness of the other five. Well, I'm worse than the Chicago committee, for I can't even agree with myself. But it may do some good to examine somewhat the merits and demerits of the two later systems. You know it is a good deal easier to talk about what others have done than to say what ought to be done yourself.

Flavor is not mentioned in the Albany grading; but Mr. Green requires good flavor in his two highest grades. I suppose, although I do not know, that the same is required in the third (or C) grade, as it says, "Honey of good quality." Indeed, if there is any difference Mr. Green's C grade must be better in quality than the previous grades, for we can hardly have "good quality" without "good flavor," although we might have good flavor without good quality if the honey were too thin.

Friend Green says, "It is undesirable* that the selling value of comb honey depends more upon its appearance than any other one quality." Entirely right. Almost any bee-keeper, for his own eating, would prefer a honey of best flavor, and rich in texture, even if the cappings were quite dark, to one of poorer flavor. Years ago I undertook the education of a grocer in Chicago. He said his customers wanted very white combs. I told him that honey was better to be left in the hives till the bees had thoroughly ripened it, and the darker shade of the comb was only a proof that the honey inside was better. I continued for some time to leave the combs on the hive, to be more fully ripened, determined that his customers should have what I *knew* was the best, and he continued to buy of somebody else. I have concluded that education in that line is a matter of very slow growth, and that it must be left pretty much to itself.

Sometimes we must deal with what *is*, rather than with what *ought to be*. However undesirable it may be "that the selling value of comb honey depend more upon its appearance than upon any other quality," I think the simple fact remains that it *does* do that very thing; and in any attempt to establish a system of grading, it will not do to leave out of consideration the demands of customers. The day may come when appearance will be of less consequence than flavor; and when it does come, grading must be changed to meet changed conditions. At present the consumer does not ask any thing further than as to the *appearance* of the article; and, whether we like it or not, we must pay some attention to his demands.

---

*Mr. Green wrote *indisputable*, "undesirable" being a typographical error. See last issue. Ed.

It is possible, however, that the graders at Albany did not altogether ignore the matter of flavor, but considered that there was no honey of light color deficient in flavor. There is a difference in the flavor of white honeys; but, if I am not mistaken, any of it is good enough in flavor to be taken by the consumer at the highest price, providing it is all right in looks.

Straight combs are demanded in friend Green's two best grades, but nothing was said about straight combs at Albany. The less cumbersome the wording in describing a grade the better, providing nothing essential is omitted; and it is a question whether one section could be found in a thousand which would be crooked enough to throw it out of a grade, if it were all right in other respects. Possibly there may be something in this that I either do not now think of or do not know about; but just as it appears to me at present, it seems hardly necessary to demand straight combs. Green's A grade demands white cappings; but that is evidently meant for one side, as afterward one side is allowed to be "nearly perfect in color." The Albany A grade says nothing about white cappings; but as perfect color is demanded, I suppose it amounts to the same.

There are other points worthy of notice, but I must defer mention till next issue.

Marengo, Ill. C. C. MILLER.

[If we understand Dr. Miller correctly, he rather leans toward the Albany grading, and will probably do so more yet after reading Mr. Elwood's article.]

GRADING COMB HONEY.

THE CHICAGO GRADING AND MISS WILSON'S CRITICISM CRITICISED.

In GLEANINGS for Dec. 15, 1891, Miss Emma Wilson writes about some of the work done at the Chicago convention, and attempts to give from memory the instructions for grading comb honey, as adopted by the convention, and then criticises the same. That any one should attempt to give such instructions from memory, was and is a great surprise to me, and especially when the apparent purpose was for passing criticisms upon them. As might have been expected, the instructions as adopted by the convention are not, in some important respects, the instructions as given from memory by Miss Wilson; and as they have become public property, and are to be "picked to pieces," it seems to me that GLEANINGS ought to find room to give them precisely as adopted, so that all of its readers may see for themselves what they are. I expected GLEANINGS would have done so before this, or I should have made this request some time ago.

Miss Wilson says that the instructions for both the first grade and second grade require that each section shall be "perfectly filled;" whereas the words "well filled" are used instead in the rules adopted, which makes quite a difference. She says each section in the second grade may have as many as three cells of pollen, whereas the word "pollen" or "bee-bread" does not appear in any of the instructions adopted. This was one of the essentials that should have been attended to, as well as both combs and wood being *slightly* soiled by travel-stain, propolis, or otherwise. Personally I should not object to these modifications being incorporated in the rules for the second grade; still, I don't believe it is for the best that any bee-keeper be encouraged to produce comb honey with more or less pollen in it, nor to have the comb and wood soiled even slightly by travel-stain or otherwise.

Miss Wilson says there were quite a number at the convention who thought there would in future be very little first-grade honey put upon the market under the instructions. On the contrary, I think there will be enough to supply the demand at a fancy price, and a great deal more than may be anticipated. And why? Because it will in future pay to produce first-grade comb honey. There are always plenty who are able to supply the demand for any commodity whenever it pays to do so.

The *color* of comb honey seems to give some bee-keepers a deal of trouble. They seem to think that only white honey should be first-class, whereas color should not, aside from being uniform, be considered at all. And why? Because some consumers prefer dark honey to white, without regard to price, when of the same grade. Now, this is not guesswork by any means. Being almost constantly in the honey-trade, and dealing directly with consumers, I know that what I have stated is true. The color of honey may be designated as white, dark, and medium. I see no reason why there should be more colors designated. This being the case, there will be only three colors to mention, or to be kept in view, for each grade.

Miss Wilson says: "Suppose you receive an order for a lot of first-class honey, and you send buckwheat honey, do you suppose the party will be satisfied?" If this party orders first-grade dark honey, he or she will, in that case, have no just cause for complaint. No one would or should ship buckwheat or any other dark honey to a party who orders white honey. Really, I see no trouble in the direction indicated. M. M. BALDRIDGE.

St. Charles, Ill., Feb. 4.

[We should have published the Chicago grading before, but overlooked it, and therefore take pleasure in giving it to our readers now, more particularly as some of its features have been criticised by Mr. Elwood.

FIRST GRADE.

All sections to be well filled; combs straight, of even thickness, and firmly attached to all four sides; both wood and comb to be unsoiled by travel-stain or otherwise; all the cells sealed, and the honey of uniform color.

SECOND GRADE.

All sections well filled, but with combs uneven or crooked, detached at the bottom, or with but few cells unsealed; both wood and comb unsoiled by travel-stain, or otherwise, and the honey of uniform color.

THIRD GRADE.

Sections with wood or comb or both, travel-stained or otherwise much soiled, and such as are less than three-fourths filled with honey, whether sealed or unsealed; and crates containing two or more colors.

The Society voted to adopt the foregoing rules as a whole, and to request the Secretary to present them to the North American Bee-keepers' Association, at its next meeting, at Albany, for consideration, revision, and adoption.

Following the above rules, Mr. Baldridge had a note, which read as follows:

Note. The color of the honey to be known as light, medium, and dark; the crates to be unsoiled; but if otherwise, the honey in such crates to be classed in the next grade below the one indicated in the instructions.

FOURTH GRADE.

All crates filled with honey not described in any of the foregoing grades.

While the Chicago committee agreed to disagree, it should be observed that the committee on grading at Albany agreed to a unit, and that the schedule, when presented in convention, was adopted as a whole. In all these discussions we must not forget the bearing of locality, and its relation to the markets.]

A. E. MANUM AND HIS NEIGHBOR.

HOW HE SUCCEEDED IN MANAGING FIVE APIARIES ALONE.

A ring of the bell brings Mrs. M. to the door.

"Good-morning, Mrs. Manum; is Mr. M. at home?"

"Yes, sir. Will you walk in, Mr. McGee?"

"Hello, Manum! what is the matter with you? Have you got the blues, or are you studying up some new invention? You seem to be in such deep meditation that I know there is a cause for it. I am sure something useful to bee-keepers or to farmers will come out of this deep study. I hope I am not intruding."

MANUM MEDITATING.

"Oh! no, Charles—no intrusion whatever. I am only too glad to see you. And right now I ought to give you a Scotch blessing for not being more neighborly. But I suppose you are very busy, like the rest of us, preparing for another season's campaign."

"Yes, Manum, I am doing a little in that line, though I am not driving business as yet."

"Well, neither am I, as I do not expect the coming season to be a very good one for honey, owing to the fact that it is the off year for basswood; and the open winter we are having I fear will injure the clovers. However, I am putting up 20,000 sections so as to be ready to catch whatever may come."

"What effect do you think the ice-storm we have just had will have on the honey crop?"

"Well, Charles, I fear the terrible sleet, with which the trees are still loaded, will cause much damage to the fruit-buds as well as raspberries and other shrubs, which I fear will lessen the bloom another year at least a half; hence we can expect but very little if any surplus next season. But notwithstanding the outlook is unfavorable, I propose to be ready to take a fair crop of honey."

"You finally did not attend the North American convention at Albany, as you intended, did you, Manum?"

"No, Charles; owing to sickness and company I was obliged to remain at home, much to my regret, and I think it a shame that more of our Vermont bee-keepers did not attend. Really, I thought a goodly number would be in attendance. But we must all make up our minds to meet in Washington next fall."

"Now, Manum, what were you meditating upon when I came in?"

"Well, Charles, I will tell you. Within the last two months I have received a number of letters from bee-keepers, asking me to give them my methods, in detail, of management the past season, without help; and not a few have requested that I give it in book form; therefore, as you came in I was thinking the matter over, whether it would be advisable for me to do so or not. There are so many bee-books before the public already that I rather hesitate about making the attempt. And, again, I can not write out my method of management for the season through to each separate individual who asks for it, as I have something else to do besides writing; and were I to do so it would take all my time."

"Well, Manum, what are your conclusions regarding the book, and why don't you give your methods in GLEANINGS?"

"There it is, Charles—that is just what I was meditating upon. On the one hand, were I to attempt to give my methods in GLEANINGS I fear the editor would cut it down so much that it would spoil the whole thing—or, at least, its usefulness—for the reason that there are so *many* little things that are worthy of mention, and, in fact, so very *necessary* to the successful management of out-apiaries—without help—that, to leave them out, would spoil all; and to publish *all* as I should wish to give it, I fear, would discourage if not disgust the editor. And, again, were I to give my methods in book form (in cheap pamphlet form) I fear the expense would be much more than the receipts; and, furthermore, I am hardly prepared to publish a book, as I am conducting some experiments which will require another season to develop; and if these experiments prove satisfactory, as I hope they will, I shall want to incorporate them in whatever I might give to the public. Hence I have concluded to defer the book business until another year at least, and in the mean time give a synopsis of my method, in GLEANINGS."

"I have wanted for a long time to ask you, Manum, how you succeeded last season in managing five apiaries alone; and whether removing the queens before swarming was a success, and just how you did it."

"Well, there it is, Charles. Like all the others you want me to give you the whole method of management from May to September; and were I to do so in detail it would take all day, and may be all night, and then you would not remember a half I would tell you, especially some of the fine points that would seem of no great consequence, but which are really of great importance. I will, however, answer your questions in part, and will from time to time give you more. First, you ask how I succeeded in my management of several apiaries alone. I answer, that the attempt was a success, though but little flesh remained on my bones at the close of the season. But I am pleased to say that I have regained 20 lbs. of the lost flesh. From the five apiaries I secured 7 tons of comb honey in sections, and 1200 lbs. of extracted. This was all secured and hauled home without help, besides caging and mailing 282 queens, and writing well, I don't know how many letters. From these five apiaries the queens were removed as soon as eggs were found in queen-cells, and in from 12 to 18 days virgin queens were given these queenless colonies. This I do by running them in the sections that are usually on at this season. I will give you more when you call again. Good-day." A. E. MANUM.

Bristol, Vt., Feb. 13.

(*To be continued.*)

[We are very glad that our correspondent has resumed the use of his pen again, and we hope he will not waste any time in the book-business. That department of bee-literature is already overdone. He will reach a far greater number of readers through the bee-periodicals, and we trust he will favor us with the items of his experience during the past summer. Details! these are just the very things bee-keepers are clamoring for. Too much of our bee-literature is made up of generalities. We once said to Dr. Miller that one valuable feature of his "Year Among the Bees" was that he told all about the *little things* that are so necessary to know. We are not at all afraid that our busy friend Mr. Manum will give too many details—the more the better. Now, instead of writing personal letters to so many individuals we trust he will tell his experience through the columns of GLEANINGS, and thus save himself a great deal of time, and do a vast amount of good besides.]

A BOUNTY NOT DESIRABLE.

ANOTHER PHASE OF THE SUBJECT.

As the discussion of "bounty or no bounty" is on, allow me to say just a few words on the negative side of the question. It seems there are three points to consider: First, if the government gives a bounty on sugar, should we not also have a bounty on honey? Most assuredly we ought; for any one who has studied the subject at all knows that sugar does compete with honey to *some extent*. Second, is it right and proper for the government to give a bounty on sugar, honey, or any thing else? I say no. The functions of government do not include the right to tax the great mass of its citizens for the benefit of a favored few. The principle underlying the whole system of bounties is wrong in the abstract.

Dr. Miller argues, with Pope, that "whatever is, is right." To many persons this kind of reasoning savors strongly of that of the Middle Ages, when monarchs claimed that every thing they did was right because a king *couldn't* do wrong, even if he tried. Again, Dr. M. says he isn't politician enough to know whether the giving of the sugar bounty was a righteous act or not. Please ask him if he has forgotten that, "for an intelligent and studious people, a republican form of government is the best in the world; for an ignorant or indifferent, the worst;" and "it is the first duty of every American citizen to study and understand economic government.

Lastly, is the bounty on honey desirable if right? I don't believe it is, because, though it would put some extra money into the bee-keepers' pockets at first, within a few years a multitude of honey-producers would arise and overstock the market, causing the bottom to drop out of already low prices. R. C. EWING, JR.

Liberty, Mo., Feb. 10.

BOUNTY ON HONEY.

NOT DESIRABLE IF NOT RIGHT.

In discussing this question on page 80, Dr. Miller's logic all rests on a good many *ifs;* and if the first *if* is displaced, his whole fabric of logic comes tumbling to the ground, as others of like character do. The fact that we have a law that *gives* two cents a pound to those who make 500 pounds of sugar or over, does not prove that the law is right. But I suppose that Dr. Miller could give no other proof of its justice except that "whatever is, is right." The righteousness of it *has* been questioned. I do not believe that our law-making power has yet advanced so far that it is infallible. I know that it once authorized and protected slavery. I know that it has legalized, and in some places does now legalize, gambling; and I know that it does to-day, in the greater portion of our country, and in every Christian nation, legalize and take its share of the profits in that crowning shame of civilization, the drink-traffic. Therefore the simple fact that a law has been enacted is not conclusive evidence that the principle recognized by it is just. But we are not left in uncertainty on the point under discussion by the courts, for we have many decisions by them, and, so far as I know, they are all to the effect that taxation for the purpose of giving bounties (excepting bounties for the destruction of wild and ferocious animals, and mischievous vermin, and the like) is not legitimate, and some of them characterize it as robbery. The State of Pennsylvania (and probably others) has prohibited it in its constitution; and no town, village, or city, can legally levy a tax to give a bounty to any individual or corporation for the purpose of encouraging or carrying on any kind of manufacturing or other business. The principle is plain and simple, as laid down by the courts, that the government can not take *my* money by taxation, and *give* to some one else. It can tax me for the necessary expenses of the government only.

Now, it is a fact that two wrongs can not make one right; and if a bounty on sugar is wrong in principle, and results in a special injury to the honey-producer by competition (which it does not), it will not make it right to enact another law on a wrong principle by paying a bounty on honey. But the only way to make it right would be to undo the first wrong by repealing the sugar bounty. But is it the *bounty* on sugar that makes it cheap? I think not. *It was taking off the tariff.* On any article that we do not produce enough of, for home consumption, a duty will inevitably increase the price, and the removal of it will reduce the price, as is proved by the removal of the duty on sugar; and the bounty has no effect whatever, except to stimulate home production.

I have dwelt entirely on the question of the justice of the proposed law, because I think, with Dr. Miller, that, if it is not right, it is not desirable; and the only thing in the article of C. F. Thomas that I can not indorse is the intimation that, although he would consider a bounty on honey a fraud on *somebody*, yet, as it would benefit *him*, he would not object very strongly to it for that reason. Let us be just as willing to do justice to others as we are to have justice done ourselves, and then we shall have that most satisfying of all things, a clear conscience. Volney White.

Findley's Lake, N. Y., Feb. 10.

QUEENS BY MAIL TO AUSTRALIA, 11,500 MILES AWAY.

A BIT OF HISTORY.

Perhaps the readers of Gleanings would be interested in a brief history of mailing queens, before any thing is said regarding the title of this article. The first queen ever sent by mail was sent out by C. J. Robinson, of New York, I believe, he sending the same to Rev. L. L. Langstroth in the early sixties. From this sprang the sending of queens through the mail, although most queens were sent by express previous to the seventies. About 1875, mailing queens became quite common; but for them to reach their destination in good order, at that time, where shipped more than 1000 miles, was the exception rather than the rule. During the early eighties this part of our business had so advanced that nearly all were successful in sending queens to all but the more remote parts of the United States and Canada. At that time I had no trouble in having nearly every queen go alive, except when sent to the more remote parts of Texas, California, Oregon, and the Northwest Territory of Canada. I can well remember the losses we had in trying for these places, especially in Southern Texas, where the queens had to endure from two to six days of staging in the hot sun, confined in a close mail-bag, on the last end of the route, when their vitality was well-nigh exhausted by the rough usage they must previously endure. I also remember what a feeling of relief came over me when, through the Good candy and a modification of our cages, I had no longer any trouble in having queens reach these more remote parts in safety. Having accomplished this I next tried sending a queen across the Atlantic Ocean, to Scotland, a distance of about 3500 miles, which went safely. This was in August, 1883, an account of which will be found on page 599 of Gleanings for that year. Mr. Cameron, to whom this queen was sent, thought this was the first queen that ever crossed the Atlantic Ocean by mail, and so wrote; but I believe later facts reveal that the honor of sending the first queen across the ocean belongs to Frank Benton, he sending them from the Old World over here. Since 1883 I have sent several queens to the British Isles and the West Indies, having little more trouble in sending to these countries than in sending to the more remote parts of our own country. In August, 1884, I mailed a queen to New Zealand, the same reaching there just alive, as is given on page 24 of Gleanings for 1885. The next trial proved a failure, as this last queen was 72 days *en route*, I knowing nothing at that time regarding the running time of the steamers which ply between here and that country. After 1885 I made no effort to mail queens a greater distance than 4000 miles, till the present season, during which I have mailed 15 to Australia.

HOW SEND?

By "how send?" I mean, shall they go by letter postage, or what is termed first-class matter, when sending queens to foreign countries, or shall they go as samples of merchandise, or by sample post? Page 72 of Gleanings for 1891, and also page 970, tells us to put on letter postage when sending queens to New Zealand or Australia, or, in other words, send them as first-class matter. If friend Root will read his third paragraph in second column on page 72 (that part of it which is taken from the Postal Guide) over again I think he will see that he made a mistake. As I read the Postal Guide and also his quotation, to all the countries mentioned previous to Australia, queens go as samples of merchandise, or as fourth-class matter, hence are not subject to letter postage, which he says we should put on. Wherever I speak of the Postal Guide in this article I mean the January edition, 1891, as, so far, the edition for 1892 has not reached us. Australia has since then gone into the Universal Postal Union, which affects the postage on letters to that country; but, if I am right, the postage on samples of merchandise remains unchanged. Page 849 of the Guide, in speaking of prohibited articles, to *all foreign* countries, mentions in the list "live or dead animals or insects," which, of course, includes bees. But to this there are certain exceptions, and one of these exceptions is the one alluded to by friend Root on page 72, where queen-bees can be sent to certain countries in cages 5x2x1½ inches. I also note that "other articles * * * may be transmitted in the mails to foreign countries * * * and exchangeable in the mails with said countries when inclosed in the form prescribed for such articles in domestic mails." Now, as queen-bees can go to the Hawaiian Kingdom (Sandwich Islands) as samples of merchandise; and as the same steamers which carry the mails from San Francisco, Cal., to this kingdom go on through to New Zealand and Australia, I take it for granted that "when inclosed in the form prescribed for *such articles* in domestic mails," queen-bees can go right through to Australia as *samples of merchandise*, or by *sample post*, if they can go through at all. Now, if I am right in this matter, the size of cage (5x2x1½) has nothing to do with queens to Australia; for if they are allowed to go there at all they will go in any cage that would be allowed in our domestic mails, and the dimensions or limit in size to such cages has never yet been fixed, that I am aware of. Taking this view of the matter, I acted accordingly, and have the satisfaction of knowing that queens by parcel post at four cents postage for each four ounces or fraction thereof reached their destination in better condition than when sent as first-class matter, as a part of the 15 were sent.

Before closing this part of the article, I wish to say that, when we come down to strict right, I don't think that bees are really lawful in the mails to Australia, and hope that some effort will be made through the Bee-keepers' Union or otherwise so that it may, in the near future, be lawful to so send them, not only to Australia, but to all parts of the world, for, evidently, the infusing of new blood into our apiaries every few years is to be of great advantage to all. G. M. Doolittle.

Borodino, N. Y.

To be continued.

[Our reasons for putting letter postage on packages of queen-bees addressed to New Zealand and Australia are found in the following extracts from Postal Guide, January, 1892, page 905:

> Queen-bees, in wooden boxes not exceeding 5x2x1½ inches in size, closed with a wire screen protected by a movable wooden lid, may be sent to the Argentine Republic, Belgium, Bulgaria, Chili, Colombia, Congo, the Dutch West Indies, the Danish West Indies, Egypt, Guatemala, Hayti, Sandwich Islands, the Republic of Honduras, India (British), Italy, Liberia, Mexico, the Netherlands, East Indies, Paraguay, Portugal and the Portuguese Colonies, Roumania, Siam, Spain, and Switzerland, as *samples*

> *of merchandise;* and to Austria, Hungary, France, Germany, Greece, Luxemburg, the Netherlands and Netherlands Guiana, Norway and Sweden, provided postage thereon is *fully* prepaid at the letter rate; viz., 5 cents per ½ oz. or fraction of ½ oz.
>
> No provision has been made for the exchange by mail of samples like those above referred to, with any foreign countries *other than those herein named.*

Italics are ours; and, as we understand it, it makes it unlawful to send queens at sample rates to New Zealand and Australia. The Postal Guide says further, page 906:

> It is forbidden to send by mail: Articles other than letters which are not prepaid at least partly, or which do not *fulfill the conditions required* in order to enjoy the reduced rate. Packets of samples of merchandise not fully prepaid at letter rates, which have a salable value, etc.

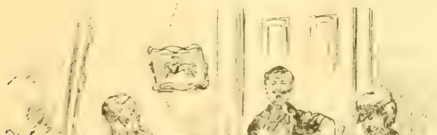
Since the two countries in question are not mentioned in the list of countries to which we *may* send queens by mail, they should go at letter rates, if at all.

We quite agree with you, that we have no direct permission to send queens to Australia, and it might be considered unlawful. We will see what can be done in the way of having Australia and New Zealand included in the countries named.]

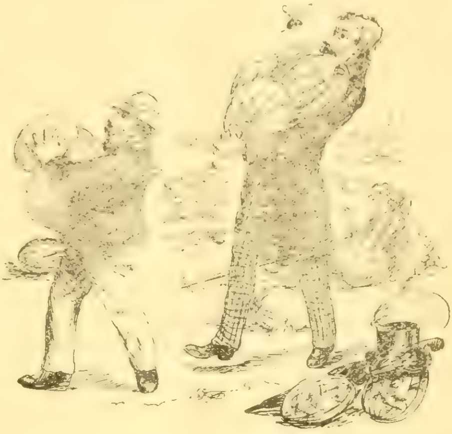
RAMBLE NO. 54.

IN THE GOLDEN STATE.

In the Sacramento Valley. After leaving Utah and the extensive white salt plains north of Salt Lake City, we encounter much the same kind of barren plains we found on the east of Utah, except that here is a stunted growth of sage bushes, and the soil is white with alkali. It was a hot day, and a little air from an open window would have been refreshing; but any one having the temerity to raise a window the least would soon feel the effects of the fire pungent dust. All night and half a day in dust was enough to endure, and it was with pleasure we noticed more thriving towns, and the rushing waters again brought vigor to vegetation. We follow the course of the Truckee River for a long distance, climbing up the Sierras, passing the noted Donner Lake, surrounded by lofty mountains, and looking very picturesque as we look down upon it from the mountain-side. It is in this region that we pass through 40 miles of snow-sheds, and at last night closes down upon us just as we reach the very summit of the Sierras. At two o'clock in the morning we were aroused and told that our long journey was at an end, and that we were in Sacramento. The rest of the night, and until a late hour in the morning, we rested sweetly in the Western Hotel. They here expect Eastern travelers will come, dust-covered and weary, and are amply provided with ablution conveniences for cleaning and polishing a fellow from head to shoes. There is even an effective pocket-cleaner in a back room, called a faro bank; and from all accounts many patronize it. The Rambler put himself through all of the cleaners except the pocket-cleaner, preferring to have his pockets filthy with what little lucre he had left.



POCKET-CLEANERS.



RAMBLER HELPING TO GATHER CANTALOUPES IN CALIFORNIA.

Having a kinsman in the city, at the head of the Pioneer Box Co., we were soon installed into his household, and were also soon busy at work in the factory running a band-saw, and making 5-lb. grape-baskets. This occupation continued about three months. The Rambler was then turned loose among the California bee-keepers.

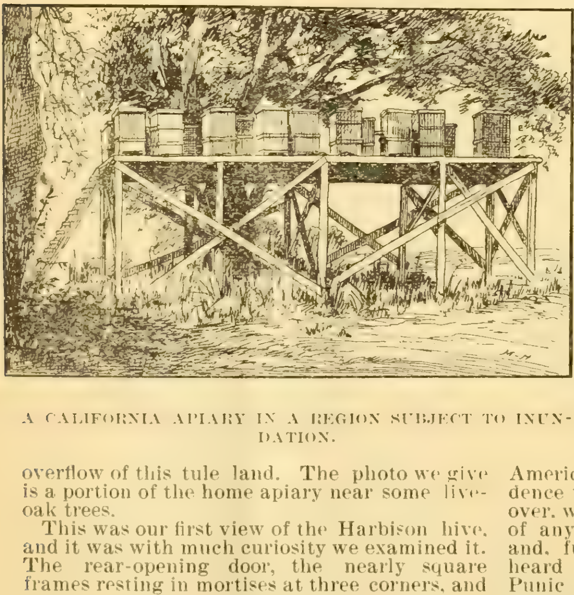
And now, my friends, I wish to say to you who have followed our wanderings in the past, that, when these Rambles commenced, we had not the remotest idea of ever seeing far-away California; and now being in the Golden State we shall not try to predict where next our feet shall wander.

California bee culture has been much written about; but as we have been into the highways and byways of California, into some of its cañons and upon its rugged mountains, and lived for a time in the lonely hut, perhaps we have received some impressions that are new, even to the readers of GLEANINGS; and if, with our photos, an occasional cartoon is thrown in, we trust the staid readers will grant their pardon. It is a sort of chronic habit we have. If any one is thinking of coming to this State to engage in bee culture these rambles will try to set the bee-keeping of California forth just as it is, and then you can take your choice.

The bees first shipped to California were located in the Sacramento Valley. It was here that Harbison won a good share of his fame as a bee-keeper. But now the Eastern man is surprised to find but few large apiaries in this portion of the State. In Sacramento City there are a few small apiaries; and Mr. Lewis, living in the city, has an apiary of over 100 colonies out in the country. The most extensive bee-keeper in the county is Mr. Adam Warner, 12 miles down the river; and learning that he had over 200 colonies, and was quite a successful honey-producer, we availed ourself of the first opportunity to call upon him. To get the 12 miles we followed the sinuous course of the Sacramento River for 20 miles on one of those boats that have a large paddle-wheel in the rear. In early times the river was noted for its purity; but now it has a very dirty and even muddy appearance. This is caused by hydraulic mining on the American, Feather, and other of its tributaries. The lands on both sides of the river are subject to overflow in the rainy season, and it is held in its course by levees.

Arriving in Clarksburg about 2 P. M., we soon found Mr. Warner's residence, and found him and his ten-year-old daughter gathering muskmelons, or cantaloupes, as they call them here, and they grow with wonderful vigor and productiveness. We could easily see that Mr. W. was in some anxiety about getting the cantaloupes picked before dark, so the Rambler got on his lot row every time, and helped finish the job.

Mr. Warner is a sturdy German, and has been upon his present ranch for 20 years. He has substantial farm-buildings, and his barn is large and much like an Eastern one, which is not often seen in this country. His honey-house was the largest and best we have seen in California. It is mounted on posts, the lower ends resting in a pan of tar to exclude ants, and it is effectual in operation. Mr. W. uses the old-style Harbison hive exclusively, and raises comb honey. There was no apiary in sight of the house, and we were informed they were out in the tules (pronounced *tu*-les). Tules are very large rushes that have a luxuriant growth upon these low lands. We found the home apiary out about 80 rods from the house, and it was the most novel apiary we ever saw. The hives were mounted upon platforms over eight feet in height, wide enough for two rows of hives, and an alley between them, with stairs at the end. Some 25 or 35 hives were mounted on these platforms, and Mr. W. had several apiaries all mounted in the same way. The reason for this high elevation is because of the annual overflow of this tule land. The photo we give is a portion of the home apiary near some live-oak trees.



A CALIFORNIA APIARY IN A REGION SUBJECT TO INUNDATION.

This was our first view of the Harbison hive, and it was with much curiosity we examined it. The rear-opening door, the nearly square frames resting in mortises at three corners, and room above for only one crate of sections, appeared to me as little better than an old-time box hive. Mr. W. was pleased with the hive, however, because he could so easily move it from place to place and carry it up those steep stairs. His hives were all made to take the old-style two-pound Harbison section; but the markets calling for the one-pound section it was with regret he had substituted them. This using a shallow crate left two inches of space above, which the bees made haste to fill also. To prevent this, Mr. W. had two-inch plank sawed just the size to slip in on the top of the crates. When asked why he did not knock off the cover and put on a rim, and put on two crates of sections, he said it would cost too much. We could see but little difference between the cost of the necessary shallow rim and the plank, while there was a certainty of getting good returns from the space occupied by the plank.

Mr. W. employs no one to attend to his out-apiaries; and to prevent swarming he practices division, paying no attention to which part has the queen. But in spite of the division many swarms absconded, and a church was pointed out that had four swarms in as many spires. A schoolhouse had several, and many dwellings were also pestered with bees in many places. During the past season Mr. W. obtained only a light crop of honey; but taking a series of years he has found honey-production profitable, even here in these low lands, and has found a ready market in Sacramento. There is much fruit near his apiaries—alfalfa, clover, and hundreds of kinds of wild flowers. We enjoyed true German hospitality for the night, and returned to Sacramento by four-horse stage the next morning, through a country devoted to fruit and wheat raising. RAMBLER.

PUNIC BEES; THEIR TEMPER.

BY HALLAMSHIRE BEE-KEEPER.

In your Nov. 1st issue you say, respecting the Punic bees, that they will sting like other bees, though it has been claimed that they won't. If you will please look up my descriptions of these bees I don't think you will find any words of *mine* that can be construed to mean or imply that they are *stingless*, or can not sting; in fact, when they have the swarming fever on they are easily provoked into stinging, but not more so than any other race under the same influence; and, moreover, they are more easily kept under control at this time by means of smoke or carbolic acid. As soon as I saw that the idea was being spread about, that they *could not sting*, I published an article on the subject in the *Journal of Horticulture* for Aug. 20th last, and I am surprised you have not copied what I say on the matter.

TEMPER OF PUNICS.

While not for a moment going so far as to say they can not sting, I do say they are the tamest and gentlest bees I have ever seen, and this includes every race that has ever reached America; putting their stings out is no evidence that they are ready to use them; moreover, when they do sting it is the least painful of any, while Syrians are the most painful; and, further than this, I have not seen nor heard of a cross-tempered stock of *hybrid* Punic bees. When going to the heather last August I nailed labels on 50 hives of Punics, without hat or other protection, and not a bee attempted to sting, though nothing whatever prevented their doing so, beyond their mild disposition.

There is only one objection I can find to these bees, and that is their color; for, somehow, I hate *black;* but this prejudice is fast wearing away after six years' experience with them. I have also now a number of other good points to add to what I have already given.

Punic bees are the future bees, where the main consideration is harvesting honey in the greatest quantity and with the least trouble, expense, or unpleasantness; in fact, I should like to guarantee any stock of bees with Punic blood in it, whether through drone or queen, to yield 20 per cent more honey, if I could have the surplus; and as virgin queens can be sold for a dollar, bred from imported mothers, with guaranteed safe delivery and introduction, perhaps mating also in the season, the gain to those introducing such will be apparent.

VIRGIN QUEENS.

You have persistently tabooed these, saying they could not be safely sent a distance and then safely introduced. For three years I have been sending out very large numbers all over the British Isles; and where the instructions I sent were followed, *not one failure has resulted.* How far I am boasting can be judged by the fact that every virgin queen I sent to America the past season, that landed alive, was safely introduced; and though Dr. Miller and Mr. Newman lost them subsequently, in a manner unaccountable to me, that fact, that, though they were *six days old when mailed*, and at least one mated and got to laying, should be proof that buying and selling virgin queens is a solved problem; anyhow, it is here, and I guess that friend Pratt has found it so too. What is now wanted is to let people understand there are parties willing and anxious to guarantee safe introduction for a stated price.

There is no jugglery in the matter. I pointed out in an article in the *Journal of Horticulture* for April 26, 1888, scientifically, both the cause of past failures and how to be successful. Virgin queens will about revolutionize bee-keeping; as, when quite understood, most will buy all their queens as virgins. Here in England I sell them at 60 cents, delivered free, guaranteed against loss in delivery, introduction, mating, or winter dysentery. I guarantee the latter, because I claim that this disease is solely the result of the way queens are reared. Each queen is six days old when sent out, so may mate in two days, and be equal to a laying queen. A HALLAMSHIRE BEE-KEEPER.

Sheffield, Eng., Dec. 12, 1891.

[We do not know that any of the advocates of Punics stated positively that such bees would not sting; but the impression left upon our minds from the reading of their articles was such. In fact, others seem to have understood it as we did. In regard to the *Journal of Horticulture*, it would be quite impossible for us to make an extract from it, inasmuch as there are very few of the foreign exchanges that we can read, and those are all in the bee-journal line. It is utterly impossible for us to cover even all the agricultural papers in this country.

We do not think the traffic in virgin queens is profitable, either to the queen-breeder or to the receiver of such queens, though there may be exceptions in cases of new races of bees, where it is desirable to test a cross, as you say the cross of the Punic with any other race is superior to the original stock. As some of our readers may not know the method by which Hallamshire Bee-keeper accomplishes virgin-queen introduction, we make an extract from one of his circulars:

> On receipt of this, prepare colonies to receive them as follows: Take three or more combs with some food in, but no *unsealed* brood or eggs, and put them in a hive; then shake into these combs the bees off two combs at least, from a good strong stock, taking care that the queen is not among them. Now remove this strong stock to a fresh stand, and set this new one in its place, which will receive most of the flying bees also.
>
> I do not advise using any of the combs from the strong stock, on account of the risk of getting one with an egg or two in it.
>
> You may prepare a colony for the queens in other ways as long as no queen or means of rearing one is left; but I find the above the most convenient and satisfactory way of any. The bees must be queenless, and have no means of rearing one, forty hours at least, or you will fail to introduce the queens we are sending you.
>
> As soon as you receive the queens drop them between the combs among the bees *after dark*, alone. On no account must they be caged, scented, or daubed with honey. In two days, sealed brood may be given them; but unsealed brood or eggs must not be given them until the queens begin to lay, or they will be almost certainly "balled" at the entrance on returning from the bridal trip.

It is no doubt the method used by Dr. Miller with success, on the queens which he received from Hallamshire Bee-keeper.]

MORE GLUCOSING.

BYRON WALKER TELLS AN ALARMING STORY.

From the comments made on the article of Mr. Tweed, page 32, Jan. 1, I see that you, in common with several other editors of papers devoted to our pursuit, are inclined to discredit the testimony given by Mr. T. As I had already repeatedly given evidence on this point at length, when this subject was up for discussion last year in the *Review*, and also in the *American Bee Journal*, I have hesitated to say any thing further until others had had their say. As you evidently have not accepted the statements made by myself at the time referred to as true, perhaps it is hardly worth while to repeat them now.

I will simply say here, that, after spending several months on the Chicago market, I fully agree with Mr. T.'s views. There are in this city alone about a dozen establishments who put up glucose honey for sale. Among them are three of the largest wholesale grocery houses in the country, one of which, whose salesman has charge of that department, informed me they sold last year 200,000 lbs. of honey. You can judge of the character of the goods sent out when I tell you that they deliver at the doors of retail groceries, in any part of the city, these goods in glass packages holding over three-fourths of a pound of the mixture, at 87½ cts. per dozen in single-dozen lots. I know what I am talking about when I say that a large majority of the grocers of this city handle such goods, and that not one grocer in a hundred keeps pure extracted honey for sale, or can be induced to buy such at a price not much higher than he is paying for the adulterated goods. Although the past season has been such a poor one for Western bee-keepers, the city markets are overstocked with extracted honey at present low prices. We may well ask, "What will the result be when there is a full crop to market?" There is no doubt in my mind that, had we such a law as you suggest, with proper provisions for its enforcement, the demand for extracted honey for table use and for medicinal purposes would be tenfold greater than it now is in city markets, and prices would be much more satisfactory. The question of the hour is, "Shall bee-keepers bend every energy to the production of honey so cheaply that glucose mixers can't undersell us (glucose is now worth less than 2 cts. per lb. in car lots), or shall we devote a portion of these energies to securing such a law, and to seeing that it is enforced when secured? Byron Walker.

QUEEN RESTRICTION.

THE EXPENSE OF SOME OF THE NEW DEVICES; BOUNTIES.

I have noticed for a while back a book advertised in Gleanings that tells all about "Queen Restriction." I sent for it, and have given it a pretty thorough examination. The great question of the honey problem of the day is, "how to produce more honey at less cost." The idea is advanced by quite a number of prominent apiarists, that this end can be attained by either restricting or altogether removing the queen, thereby preventing swarming. I remember reading an article in the *Review* of June, 1891, from Mr. Aikin, of Colorado, who, while living in Iowa, I think, practiced the removal of queens at the beginning of the honey season, and allowing the colonies to rear another queen, by which method claiming to increase his honey product very largely, and also preventing swarms. For increase he gave the best old queens a frame or two of brood and allowed them to build up.

Now, this is an interesting question, not only to myself but to many of the bee-keepers of this county, and, I think, to the fraternity everywhere. For this reason I wish to discuss the claims advanced for queen restriction, and will leave the queen-removal plan to be discussed by Mr. Aikin and others who have tested it.

In the pamphlet before me on this subject, the author claims for his restrictor (which confines by queen-excluding zinc the queen to one or more frames. He seems to think four frames about the right number), that, by its use, he can get a much larger yield with much less labor than by the plan of removal. He comments to a considerable extent upon the backbreaking process of removing queens and cutting out queen-cells. We are all well aware of this fact, and I have never found any more disagreeable job, during the hot days of June, than that very thing. But the average beeman expects work, and lots of it, so we must offset the work by the cost of the restrictor. For a four-frame restrictor the price is 69 cents each, or $6.70 for 10. It strikes me that, in a large apiary, that would be quite expensive.

Now, on the other side, take the labor on ten hives. By my plan of removing queens I want only ten minutes to each colony, and fifteen minutes for cutting out cells. Of this plan I may write further before the honey season. However, we will allow thirty minutes, so as to give plenty of time for each operation. That gives one hour for each colony, to remove queens and cut out cells. At $2.00 per day the cost for the ten hives is just $2.00 for ten hours' work. But I claim that the young queens raised by this method would be enough better to more than compensate for the day's work. Am I not right?

I do not desire to disparage the queen-restrictor. I am simply counting the cost, and that must be done, in order to solve the problem.

I may also state, in behalf of this method, that the author advises wide frames and sections in the lower story in connection with the restrictor. I have never tried getting honey from the lower story, but we have lots of men who have tried it. Let them tell us something about it. I hope this will provoke a general discussion all along the line upon this question, as I am sure that it is an important one, and I for one want to weigh the evidence before the season opens. After working-time comes we can operate on a more matured basis.

AUTOMATIC SWARM-HIVERS.

In these we have another "restrictor;" and while they may eventually be perfected so as to fill the bill, which does not seem to be the case yet, still the question of cost must be considered. In the most of these devices it is necessary to provide an extra hive, whether it will be utilized or not, which of itself is quite an expense, and, to my mind, an unnecessary one; for if we are to produce the most honey at least cost we must avoid swarming except for desirable increase. The device itself, also, is too much expense to be used in an extensive apiary when there is so much uncertainty as to whether many swarms will issue or not; therefore, in summing up I must incline to the belief that dequeening has the floor.

BOUNTY.

And now, as if there were not enough troublesome things to perplex the bee-keeper, up pops an entirely new idea. I want to say that I am opposed to bounties. If the government had given sugar industries and capitalists a bonus and a stipulated sum for the first 100,000 lbs. produced, and then stopped at that, and at the same time limited the time to five years or less, then the matter would have been disposed of in a comparatively short time, and prices would have become settled, and experimenters and investors would have been amply remunerated for advancing the industries of the company. But as it is, the thing may go on indefinitely, and finally become a bone of contention between the political parties, and then—God have mercy on us! Another thing about "boosting" up any particular business or pursuit, is, that it is apt to cause prejudice in the minds of consumers and thereby defeat the object aimed at. Bee-keepers generally depend upon a local market, which renders them a mark of displeasure on the part of those not benefited, which would not be so much shared by their more distant colleagues, the sugar-producers. We as honey-producers would better bend our energies to have the sugar bounty arranged as mentioned than to try to offset it by another bounty on honey. S. A. Dyke.

Pomeroy, O., Feb. 8.

[It seems to us that our correspondent has been too liberal with his time in hunting up queens. We have on several occasions in about two years, opened up, found the queen, and done such other work as clipping wings and tearing down queen-cells, at the rate of about forty hives in two hours. Some of these colonies were two-story. We did not examine all the brood surface, but went through the hive pretty thoroughly—a thing we like to do once or twice during the season. This would allow only three minutes per hive; and yet we do not think we particularly hurried to get through the work. But, as we have before explained, we can, a good share of the time, diagnose the colony with little or no frame manipulation.

We rather hesitate to speak about the cost of queen-restrictors, because it might appear that we were interested in pushing the sale of our own articles; and we will only add that the object of queen restriction, advocated by C. W.

Dayton, is primarily, as we understand it, to control unnecessary brood-rearing out of season, and thus prevent a large force of consumers at a time of year when there is no honey to be gathered. Just how far it will prevent swarming we are not able to say.

THE OHIO STATE CONVENTION.

DR. MILLER'S REPORT OF IT.

The Ohio State convention at Cincinnati, Feb. 10-12, was different enough from the previous meeting of the same society, so far as members in attendance were concerned, to have been a meeting in a different State. But Ohio is a good-sized State, and Cincinnati is at the southern extremity. The meeting was not unwieldy on account of great numbers, but there was no lack of interest from beginning to end. Some matters came in for more discussion sometimes than they probably would have had if the veterans had been out in fuller force.

I hadn't seen the president, C. F. Muth, for several years, and was surprised not to find him older looking. One thing that undoubtedly helps to keep him young is the fact that he has a son so competent to take his father's place in business matters, and this allows the father less anxiety and more outdoors. At one of the sessions of the convention Gus came in to speak to his father about something, in a whisper; and as he did so, standing behind his father's chair, he stooped forward and put his hand on his father's shoulder and partly about his neck in that easy, good-natured way that said more plainly than words, "We're old cronies, and fully understand each other." It did me good clear through.

That same long-geared German, C. F. Muth, is a thoroughly well-posted bee-keeper, and you can not hear him take up any topic in bee-keeping without being likely to learn something from him. He mentioned an item as to shipping bees that I do not remember to have heard before. He has had a good deal of experience in having bees shipped long distances from the South; and his instructions are, to move to a new location any colony to be shipped so that it may stand there a day or two before shipment, and allow its flying force to go back to the old location. This leaves only young bees to be shipped, and he says they will stand a long confinement. I believe he allows another colony to be on or near the old stand, to catch the returning bees, and I'm not sure but he sometimes may allow young bees from other colonies to be shaken in front of the one to be shipped.

Without attempting to give any report of the convention, I will mention some of the points that seemed of special interest. It was asserted that, when bees work on asters, a sour smell is readily discernible, even at some distance from the hives, something like the smell of old sour milk.

Rev. L. Johnson said aster honey was all right till frost; but if bees worked on it after it had been frosted, such honey was poisonous to them.

In peddling extracted honey in the city, Mr. Titus, instead of weighing it, measured it out in a pound or a two-pound bottle, letting the purchaser furnish his own dish. Some honey would stick to the bottle each time, but his honey didn't any more than hold out in weight, because the amount tasted in sampling balanced what stuck to the bottles.

Quite a discussion occurred as to how much help the bees should have in cleaning out their hives in spring. Mr. Muth said he had given up helping the bees clean house, as he found much of the snuff-like material found under bottom-bars was wax which the bees used over again to cap their brood. Mr. Haines held that it was mainly fæces, and asked bee-keepers to note whether, in the spring, such material was not always found directly under the cluster, instead of under the outside seams, where some argued it would be found, dropped by the bees as cappings gnawed from the outside combs in uncapping them.

The unjust railroad rates on extracted honey were ventilated. Mr. Muth said it cost $1.50 to get a barrel of molasses or syrup from New Orleans to Cincinnati, and $5.50 for a barrel of extracted honey. The difference between the two, if it had any effect on the rate of freight at all, should be in favor of the honey, for honey is a little heavier for the same bulk, and, if granulated, not so likely to leak.

Comparing the different kinds of comb honey as to toughness of comb, Mr. Muth said linden comb is very tender, hence liable to be broken in shipment; clover not so tender, and alfalfa very tough.

A bee-keeper had shipped honey to Mr. Muth in a glucose-barrel, the barrel showing what it had previously contained; and this barrel, being seen at his place of business, had secured for him a little free advertising in the newspapers, for which he was not anxious.

Moral.—Don't ship honey in any thing that *looks* like adulteration.

At this convention I had occasion again to notice the importance of having outside conditions all right at a convention. The meetings were held in a hall having the very common fault of being too large, making it very difficult to hear some of the things said, even if all were perfectly still, and the difficulty was further increased by the hall facing on one of the principal streets with its constant rumble and rattle. On the second evening the session was held in a comparatively small inside room, from which the noise of the street could not be heard. The contrast made a very favorable impression in favor of the smaller room. C. C. MILLER.

Marengo, Ill., Feb. 23.

LADIES' CONVERSAZIONE.

ALSIKE CLOVER.

ITS VALUE, AND HOW TO RAISE IT.

The value of alsike to the bee-keeper makes it worth his while to extend its culture in every way possible. In inducing his farmer neighbors to grow it he not only benefits himself but also his neighbors as well. Few appreciate its value. Rightly managed it may be made to yield three products—honey, hay, and seed, which, in a little more than a year, are equal in value to the land on which it grows.

With suitable soil, and in competent hands, ten bushels of seed to the acre is a possible yield, which, at the present prices, $7.50 to $9.00, will purchase an acre of good farming land almost anywhere. There are, besides, the hay and honey.

When the cultivation of alsike is recommended to farmers, one or more of the following objections are usually offered: 1. It does not germinate well; 2. It does not produce a paying crop of seed; 3. It does not produce as much hay as red clover; 4. The hay is of inferior quality. If fed to milch cows, the butter produced is white.

In the first case, either the seed was poor or the ground was not in proper condition. A sample of seed should be tested before purchasing.

In the second case, a short crop of seed is generally due to a lack of judgment as to the right time for cutting, and to improper handling afterward. .

In answer to the third objection, it may be stated that, though the yield of hay may not be as great, the value of the whole product is greater.

Finally, the hay is better than red-clover hay, the stems being less woody, and devoid of the fine hairs which render red clover hay "dusty." In this market, timothy mixed with alsike is beginning to be rated No. 1, while timothy mixed with red clover is No. 2. As to its effect upon butter, a few roots, carrots or the like, fed to cows will remedy that. Often failure is the result of making a trial on so small a scale that the crop is neglected; then the grower thinks, of course, it is "no good."

A neighbor, Mr. McCall, has given to the alsike-clover plant the same kind of intelligent and careful study that Mr. Terry has given to the potato, with equally satisfactory financial results. Mr. McCall is too busy "compelling success" to write of his methods for the benefit of others; so, believing that they would be interesting and profitable to many, I interviewed him one evening. The following are the facts brought out:

Mr. McCall raises alsike for the seed, so his methods accord with his aim.

The most suitable soil is a clay loam, with a good proportion of the vegetable matter; but it may be grown on almost any kind of land.

The land, having been deeply plowed and thoroughly pulverized the previous autumn, and sown to wheat, is harrowed in the spring with a fine-toothed harrow—an operation greatly benefiting the growing wheat. The clover seed is then sown at the rate of 8 to 10 pounds to the acre. A lighter seeding is often recommended, but Mr. M. believes that better results on the whole are obtained by a more generous seeding. The sowing should be done as early as possible, so that the seed may catch some of the spring rains. Here, the first of April is about right. It is important that the seeding be even. Bare spaces certainly lessen the crop, while overcrowded ones do not increase it. It is by attention to small details that success is won in this as in any other undertaking. If the seeding is done by hand, mixing the seed *thoroughly* with several times its bulk of sand may aid in its even distribution.

The seed may be sown with oats, if preferred, provided the ground can be put into proper condition early enough.

Soon after the removal of the wheat from the ground, the young clover-plants should cover it. They often make such growth as to blossom and mature seed the first season. Possibly, by sowing the seed alone, and under the most favorable conditions, a fair crop of seed might be obtained the first season; but the second season is the one depended upon for the main crop, under ordinary circumstances. In the autumn and early spring the field may be lightly pastured, preferably by sheep, but care should be taken to remove the stock before damage is done. By early June the clover-field should be a sheet of vivid green, with no earth visible. Later, the pink and white blossoms appear, borne at the ends of the main stalk and branches. This is the bloom which will furnish the largest and best part of the seed crop. Keep watch of them, for they soon disappear under a set of somewhat smaller blossoms, which in turn give way to another, the bloom continuing several weeks. During this time the bee does double duty in improving the yield of seed by cross-fertilization and in gathering the nectar with which the florets are abundantly stored. Mr. M., realizing the value of its labors, purchased ten colonies, and feels that they paid for themselves in the first season by increasing the yield of clover seed, to say nothing of their gathering 300 lbs. of the finest honey in the world. Had he been an experienced bee-keeper, instead of the beginner that he was, the honey crop would have been twice as great. A week or more of bloom passed before the boxes were put on at all.

To go back to those first clover-blossoms—they will have become a rich brown in color, and *nearly* dry. Now is the time to cut it. Just here is where a day's delay means partial if not total failure. Waiting for the later and inferior heads to ripen, the earlier and more valuable ones, becoming *entirely* dry, burst their pods and scatter the seed upon the ground. When cut at the proper stage, a large part of the foliage is green and tender, and, with the immature heads, furnishes a hay equal if not superior to that from the first growth of red clover.

After it is cut, moisture does not injure alsike as readily as it does other hay. To avoid scattering the seed, the hay should be handled as little as possible during the curing, and then only when there is moisture enough in the atmosphere to keep the stems pliable—never in the heat of the day. This is the second point of extreme importance. Drawing should be done during the earlier part of the day, after the dew is off, and again in the latter part of the afternoon. Subsequent operations need no comment until the seed is ready for the cleaning process. In order to command the highest price in the market, the seed must be perfectly clean; but as it is so much smaller than any other seed which a farmer handles, the fanning-mill requires finer screens than those ordinarily used, and the blast controlled so that seed is not blown off in the chaff. Though it requires skill and a good machine to perfectly clean seed without waste, care and ingenuity will often accomplish the desired result with slight expense, and add many dollars to the value of the crop.

The first seeding may be allowed to remain on the ground during the third and fourth seasons, and possibly fair crops may be had; but, on the whole, it is probably better to turn it under after the first cutting, and use the ground for some other crop—potatoes for instance.

The past season was an exceedingly poor one for clover in this locality; but alsike yielded double the amount of seed obtained from red clover when the latter was worth the cutting. Many did not cut it at all.

Flint, Mich., Feb. 15. EMILY E. WEST.

WAX FLOWERS.

MRS. AXTELL TELLS HOW TO MAKE THEM.

As bee-keepers are the producers of wax, it is very befitting that their homes be adorned with wax flowers, which imitate the natural flower more nearly than any thing else. Often, when I have been making flowers, some one would come in, not noticing the material and tools, and remark, "What pretty flowers!" I would hand them to them, and tell them to smell of them, which they would do, thinking they were natural flowers; but the smell of the wax would reveal their nature.

To make a large wreath, a glass the size of 22x24, three packages of single white wax sheets, one of double-strength white for pond-lily, one of red, one of green, one of yellow, and one of orange, will be required. The wax costs about 12½ cts. per package of 12 sheets, and that and the other supplies can be purchased at almost any large drugstore. If not on hand, the proprietor will order it. Be careful to order pure white wax—not dingy or cream-white.

Other colors may be used if desired, but I think a wreath looks better without solid blue, purple, or pink colors, and but little yellow. Colors can be shaded by mixing more or less arrowroot with the paint, which will give a bloom or velvety appearance to the flower.

Two little round-headed tools to mold the petals into shape will be needed, one of the heads about as large as a hazelnut, and the other the size of a hickorynut, with handles two inches or so long, one sharp-pointed, and the other rounding; also a bunch or two of red and yellow stamens for the center of the flowers. Sometimes those can be found in old artificial flowers in the house. Strips of yellow wax, fringed finely, will answer for many flowers. You will also need five cents' worth of powdered mica (called also diamond dust); one cent's worth of coarse wire, about twice as stiff as broom wire; one cent's worth of broom wire, and the same of Prussian blue; English carmine, a dime's worth; four or five leaf-molds, such as a rose-leaf, a small ivy-leaf, suitable for making a white cross, and some larger leaves, as camelia, pond-lily, and maple.

The room to work in should be warm, so the wax will not break—rather more than comfortably warm in winter weather, choosing days to work when the wind is not blowing.

Take natural or artificial flowers and pick to pieces, and cut patterns from them. Have another flower, as nearly like it as possible, to pattern after, or fashion them after flowers in paintings. After one has made a wreath, using some colored wax, then he might learn to paint and tint the wax instead of using one solid color, as I think flowers thus made are more natural and delicate in color than when of one solid color, which is done by rubbing the paints on the under side of the white wax petals, or on the center end of each petal, leaving the points white, or just tinted. Do not get any paint or bloom upon the base of the petals, or they will not stick to the stems. Colors can be shaded by mixing more or less of the arrowroot bloom with the paint. If the bloom is used, the diamond dust will not stick well, or vice versa. The diamond dust, or powdered mica, is to give it a sparkling appearance like frostwork.

To make a rose.—From three sheets of wax laid evenly together, having first been wet to keep from sticking, cut fifteen or more petals, thus cutting three at a time, with scissors loose in the rivet (although any scissors will answer). Before picking the edges of the petals apart, smooth them by rubbing around them a little with the finger. For the stem of the flower, take a piece of coarse wire, about twice as large as broom wire; loop one end down to keep the flower from being pulled off as it works off the wire. In making, cover loop with yellow sheet beeswax pressed into a little oblong ball. Stick on to this fifteen or twenty yellow rose-stamens, or some boughten yellow sheet wax fringed very fine, and firmly wrapped around and curled toward the center. Now stick on more pieces of yellow beeswax; then proceed to mold the petals. Lay one by one in the palm of the hand, and, with the point of the molder, curl the small ones. The larger ones should be molded with the head of the molder. The center petals should curl toward the center, and the others made to curl gradually outward until the last leaves curl toward the stem.

For half-blown buds, make the same as a rose, only more closed, and leave out the stamens. For a closed bud, put wax upon a looped stem and a few petals closed. Put around the buds some green leaves cut like the letter V, and rubbed lengthwise with a molder so as to curl over the bud. Press smoothly around the stem. Now put on green wax enough to make a bud-shaped base for the buds, and press and roll until neatly finished. A little natural green moss stuck on adds to its beauty. Join all together, adding green leaves and one autumn leaf, and cover the stem with strips of green wax. Copy from nature as much as possible.

Camelia and buds are made the same as the rose, but cut the petals nearly as large again, and as many more. Use camelia stamens, or a little white wax fringed, and dipped in carmine.

For dahlia, make a heading as large as a small acorn, on stiff wire, with a little yellow or pea-green fringe in the center. Put on twenty fine petals, twenty a size larger, and forty still larger. Both sides of the petals curl up and around, and touch at top. Press flat at the point where stuck to the stem. A little red paint on the fringes, and rubbed on the under side of the tips of each petal of a white or a yellow dahlia, is pretty; or, rub the paint on the point where it sticks to the stem, showing just a shade of color in the dahlia when finished, leaving the points of the petals white.

For fuchsia, take a piece of wire five inches long. Cover it with green wax; bend it down a little; loop, and stick on a little heading of green or yellow wax; then six long stamens, one in the center a little longer than the rest; or, use fuchsia-centers, then cut four small white petals hollow in the center, with the small molder; stick them to the stem standing up, showing three-fourths of an inch of the stamens. If possible, have a real flower, or the picture of one, to look at. Now cut six long petals; roll lengthwise with the small molder to curl them back. Lay a little fold in each petal where it touches the stem, to give room for all the petals, and to make them strong. The long and small petals should be of different colors; as, purple for the center, or standing petals, and scarlet for outside; or pink for center, and white for outside.

Bridal wreath is made very much as is the fuchsia. It should be of white or lemon color. Leave out the small petals in the center, adding long and drooping stamens.

In the next issue will be directions for making fruit-blossoms etc., and for framing the wreaths when done. Mrs. L. C. Axtell.

Roseville, Ill.

VENTILATING OUR HOMES.

HOW DR. C. C. MILLER "RAISES THE WIND."

Some time ago the subject of having our homes comfortably heated and at the same time well ventilated was discussed in Gleanings. It seemed a somewhat difficult problem to solve—to do this for any thing like a moderate sum. Dr. Miller has considered the matter of pure air of so much importance that we have always used the open-grate Franklin stove, and on no account would he think of having a base-burner, as he could not tolerate the bad air.

Would you believe it? This winter he has a new base-burner, and we have taken an immense amount of comfort with it too. But this stove, the Howe ventilator, is radically different from the ordinary base-burner in the matter of pure air. It takes the place of three stoves—heats the sitting-room, dining-room, and an upstairs bedroom, and could be made to heat more if necessary. It is very easily taken care of. It simply needs to be filled up and the ashes taken out every morning, and it's all right till the next morning. It is so much cleaner than the Franklin, or Low-down, as it was impossible to keep things free from dust with that, dust as often as you might!

But the best of all is the pure air. The air in the house is as good as that outdoors, and no headache in it, as with the ordinary base-burner. There is a cold-air pipe passing through the cellar wall (it may pass through a cellar window) and up through the floor, directly under the stove and into the stove. There is a current of fresh outdoor air passing constantly through this cold-air pipe into the stove; and, being heated by its passage through the stove, it comes out into the room as warm air. Of course, this fresh air does not go into the fire, as in that case there would be smoke and gas in the room. It passes up through outside chambers something like the dead-air space in a double-walled hive. There is also an arrangement at the lower part of the stove to carry off the foul air. One need only to look at the rich dark-green foliage of our house-plants, that look almost if not quite as luxurious as if growing outdoors, to know that the air is pure. Next to the pure air is the saving of labor. Before we got our new stove we had a large wood-stove in the dining-room, and a small coal-stove in the room upstairs. Now they are both taken down. Think of the amount of work saved in not having to run those two stoves, to say nothing of the dirt and dust they would cause, which is no small item! Folding-doors between the sitting-room and dining-room make it easier to heat the latter. The room upstairs is heated by means of a hot-air pipe passing through the ceiling, terminating in a small register. This room is warmer than it was with the small stove. The air that comes out of this register is not air that has already been used in the room below, but is fresh air that has come directly from outdoors, merely heated in its passage through the stove.

The stove, set up ready to light, costs just an even fifty dollars. We think that, in two winters, that amount will be saved in fuel, to say nothing about what is gained in health and comfort.
EMMA WILSON.

Marengo, Ill.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

PROTECTION VERSUS NO PROTECTION FOR OUTDOORS.

The question of winter protection can not be emphasized too strong. Not having the pleasure of a cellar, my bees winter on their summer stands. With good windbreaks both north and west, the loss for several winters (with the mild winters too) has been small indeed. The ten-frame Simplicity hives have the upper story filled with leaves. These are in fine condition, and have hardly any traces of diarrhea. The one-story Simplicity (eight-frame) hives are placed inside of goods-boxes, with leaves around and above the hives. These are going through the winter in excellent shape. A few are left on summer stands without any protection whatever. These are eight-frame one-story Simplicity hives. These are having a rough time of it. The diarrhea has overtaken them, and death is certain.

Colonies well protected are doing well in spite of "bug-juice" for winter stores. For me to meet a cold winter successfully I would have plenty of bees hatched in August and September, little or no pollen, bees put on eight-frames, plenty of *good* honey—not "bug-juice"—six to ten inches of leaves all around the hive, except the fronts and bottoms, and the entrance open full width. With this arrangement no fears need be entertained because of a severe winter.
J. F. MICHAEL.

German, O., Jan. 25.

[You have given us good proof of the value of protection. Our experience so far confirms it. For us, colonies in a cold winter outdoors unprotected won't live until January.]

ADVANTAGE OF SEALED COVER AND WIDE ENTRANCE FOR WINTERING.

As the question of absorbents over the brood-chamber is now being agitated I will add my mite. Some four years ago I wrote the senior editor of GLEANINGS, that, from observation of the effort of bees, I was led to believe an air-tight covering better than a porous one, and that, acting on that idea, I had utilized the leather from our family carriage, cutting it to fit neatly and applying it early, directly on the frames, and letting the bees propolize all air-holes. This with three hives. They came through well, and built up early. A fair-sized chaff cushion was placed over the leather. He replied that the leather was porous. He might have thought differently had he seen it. The following autumn I ventured on seven with leather for covering, and over this a close-fitting ⅞-thick white-pine board, and over all several newspapers, and on them the canvas used during the season. This was in the latter part of October. Of course, in all cases I used chaff over all. I now aim to have all hives as near air-tight, except beneath, as I can. Without being tedious I will say, loss none thus far; but the great advantage I claim for the method is, early brooding and no spring dwindling. My top-bar has a passageway for the bees, and I thereby avoid the use of a honey-board.
W. S. ADAMS.

Guys, Md., Feb. 9.

MANUM EXPLAINS ABOUT THAT HONEYMOON.

Friend Root:—You may say to our Canadian friend, Mr. F. J. Miller (page 104), and others, that A. E. Manum has *not* fully recovered from his "honeymoon season," and hopes he never will, trusting that said "honeymoon" will continue to shine in her fullest splendor. Nevertheless, Mr. Editor, I will endeavor, in a very few days, to respond, through GLEANINGS, to the many calls from our friends. I have been so busy since last May with the bees, house-repairing, and entertaining visitors, to say nothing of the "new queen," that the readers of GLEANINGS have necessarily been neglected. Thanking them all for their confidence and kind words, I remain

Yours truly,
A. E. MANUM.

COLORADO; SNOW TILL YOU CAN'T REST.

I once more find time to send in a few lines from this part of the moral vineyard. It is winter—winter in good shape—snow till you can't rest, if I must use the expression—any way, snow all over every thing—hill, mountain, and valley. The largest snow of the season fell on the 4th of this month. If snow is a sign of a good honey year, this has the appearance of being one of unprecedented greatness, for we have had more snow than we had last year. The past season would have been a good one but for the heavy rains that came just as the honey-flow was coming on. I have been keeping the snow away from the front of my hives. The last time I was out I was wondering to myself how many of the brother bee-keepers were attending to the same business I was. When I scraped the snow away, how they buzzed, just as if they were glad that I was attending to them, and they wanted to let me know it.

In looking over Gleanings I see a great deal is said about combining bee-keeping with other business, and the best kind of business to carry along with it. I do not want to bring up any thing to make arguments; but if it is not out of place I would like to tell what I expect to do this season: I am going to combine gardening with bee-keeping, and raise a large lot of onions, in connection with taking care of about 30 or 35 old colonies and the most of the new ones.

Greeley, Col., Feb. 18. T. V. Jessup.

[We should be glad to have you report your success or failure.]

TO THE CALIFORNIA BEE-KEEPERS.

Through the influence of Prof. A. J. Cook, California bee-keepers may join the State Association by simply sending 50 cts. to the Secretary, J. H. Martin, Riverside, Cal. All the readers of Gleanings know him as the "Rambler." California can not support a bee-journal, but we can have a large State association, and I would urge every reader of Gleanings in the State to send 50 cts. and become a member. Even if you can not attend the conventions you can vote by proxy, and will receive the printed matter sent to members. The dues are only 50 cts. per annum, and it is worth that to be in touch with the leading bee-keepers of the State.

Fillmore Cal. J. F. McIntyre.

[The following is a clipping which friend McIntyre sent along, which will speak for itself:]

ORGANIZATION OF A CALIFORNIA STATE ASSOCIATION ELECTION OF OFFICERS.

The bee-keepers assembled again yesterday morning at 9:30 o'clock, and proceeded to organize a State association, to be known as the California State Bee-keepers' Association.

The following officers were elected: President, J. F. McIntyre, of Fillmore; vice-presidents, L. T. Rowley, of Los Angeles County; F. H. Hunt, of San Bernardino County, and J. A. Odell, of San Diego County; secretary J. H. Martin, of Riverside; treasurer, G. W. Brodbeck, of Los Angeles.

The Executive Committee will consist of the officers of the association, and Messrs. Allen Barnett, of Whittier, and J. W. Strong.

The association starts out with a membership of forty-three, besides three honorary members, Prof. Cook and Mr. and Mrs. A. I. Root. The next meeting will be held in Los Angeles, at a date to be fixed by the Executive Committee. An opportunity was given the gentlemen to become members of the Bee-keepers' Union, and thirteen joined.

In the afternoon Prof. Cook gave a most entertaining talk on the anatomy of the bee. The professor is a fascinating speaker, having been all his life a close student of nature. He has studied carefully all the various creatures of the animal kingdom, and unhesitatingly pronounces the honey-bee the most wonderful of them all. After listening to his interesting address yesterday it was not at all difficult to see how he has so satisfactorily filled a chair in the Michigan Agricultural College for years. He developed the fact that there was more satisfaction in bee-keeping than merely that of dollars and cents. This examining so closely into nature makes men purer; and the further he delves into her secrets, the closer is he drawn to all her creatures.

After an interesting address by Mr. Root the association adjourned.

WHAT DR. TINKER THINKS OF THE NEW HOFFMAN FRAME.

Friend Root:—I believe you Medina folks are upon the right track in sticking to the L. frame, and not advocating a closed-end frame. As you now have it, it is simply a fixing and spacing device to keep the L. frames in place. I do not believe that there is any form of closed-end frame that will ever become popular.

New Philadel'a, O., Feb. 4. G. L. Tinker.

THE NON-BURR-COMB FRAMES.

Ernest is right on frames. I put on 200 Hoffmans last year, and they are the best; also 400 ⅞ x 1⅛ top-bar frames, and had no burr-combs.

Mt. Pleasant, Tex. G. W. Bristline, M.D.

THE COLORADO STATE BEE-KEEPERS' ASSOCIATION.

A. I. Root was with us when we organized, and helped to make our meeting a success. We shall miss him at our next meeting; but we can rejoice to know that our loss will be *gain* to others, where he may chance to be. Since I first met Mr. Root last November, how often I have wished that this world were full of just such good Christian men! From what little I have heard him say, and from all his writings, it would seem as though he is for ever battling against sin, and doing something for the cause of Christ. J. A. Arbuckle.

Greeley, Colo., Feb. 15.

PROPOLIZING THE HOLES OF PERFORATED ZINC.

I have been very unfortunate this year with my bees; for, though I have not lost any, yet I have not had one spoonful of surplus honey, although excellent gatherings are reported by neighbors not over three miles distant, on the creek low lands. I have had a curious experience, which may make you smile. Owing to the fact, I think, that my range is poor, and my bees, of course, have more time than they know how to use rightly, they have got into the habit of propolizing heavily; and in order to offset that I used this year zinc excluders, but, so far from being a success, I find that all the colonies but one have propolized the holes in the excluders until they are all stopped up. Of course, had they had any honey the case would have been different; but as it is, it looks somewhat comical. I suppose they do it as an amusement or pastime. A. Sion.

Kyle, Texas, Dec. 28.

[Your experience with the perforated zinc has been quite unusual. Has any one else had a similar experince?]

A NOTE TO A. I. ROOT.

I have been greatly interested in "Notes of Travel" from A. I. Root, and wish to enter an earnest wish that he may extend his trip to Florida and thence to Cuba—most especially to Cuba. Tell him not to be in a hurry to return to Medina. The improvement of his health is a matter of great importance to his patrons, as well as to himself and family. I think there are over 10,000 people who will agree with me in the desire to have him prolong his journey so as to give us some interesting notes direct from Florida and Cuba, the lands of flowers and honey. Don't come home till April, A. I. I also hope that Rambler was rescued from drowning in the gulf of California, and that the junior editor of Gleanings did not get a *header* from his bicycle. A. P. Fletcher.

Ludlow, Vt., Dec. 15.

LIGHT BROOD VS. HEAVY BROOD FOUNDATION FOR THE BROOD-CHAMBER.

Friend Root:—I have noticed you rather favor the use of thin foundation for brood-chamber. There certainly is a great difference in locality. We often have a great scarcity of honey the last of May and first of June, and I have been troubled very much by having the thin foundation eaten full of holes, and I believe it will stretch some, even when it is wired, and there will be drone comb drawn out. I would not use thin foundation in brood-chamber if the medium or heavy cost double price; and I never put in foundation without wiring. What use is there in saving a little expense and failing to accomplish one of the objects of using foundation—viz., to prevent drone comb? It can not be too thin for sections. J. F. VAN PETTEN.

Linn, Kan., Jan. 27.

THE M'KINLEY BILL, OR ADULTERATED HONEY AND LOW-PRICED HONEY.

It is almost impossible to sell honey not strictly first class. The McKinley bill has done us incalculable injury; and if something is not done soon to right the wrong done us, profitable bee keeping will be a thing of the past. Why are not steps taken at once by the Bee-keepers' Union to lay the matter before the proper committee of Congress? EMIL J. BAXTER.

Nauvoo, Ill., Feb. 1.

[While the low price of sugar, as provided for in the McKinley bill, may have some effect on the price of honey, it is only slight in comparison with the way some packing-houses are putting up glucosed honey and calling it the pure article. It is quite useless to attribute all unpleasant business phenomona to the McKinley bill; but against these adulterated goods on the market, bee-keepers must rise and do something. We were quite disinclined to believe there was any such disreputable business going on; but facts coming in are opening our eyes somewhat. See editorial comments elsewhere].

Whenever it is a little warm, the bees come out of every hive and mark all over the ends of them as they do in spring, and a large lot of them fall on the snow and die, and I am afraid that I am going to lose them. What shall I do to prevent the slaughter of my bees? I have thought sometimes I would put a wire screen over the entrance, but have been fearful to do so. My hives all stand on the north side of my house, but all face the south. Although they are somewhat shaded with trees and vines, the sun warms them quite readily.

Kent, O., Feb. 2. H. W. DONCASTER.

[Bees are quite apt to fly out and die as you describe. We think nothing serious will come of it unless your hives have bad or poorly ripened stores. If the entrances are shaded the bees would be less liable to fly out. Whatever you do, don't shut the bees in.]

SUCCESS WITH DOOLITTLE'S METHOD OF REARING QUEENS.

We can not see how any one can fail to raise queens by Doolittle's plan. We have had a poor year, and yet we have never tried a colony and failed. We have always raised some cells (on an average nine), and we considered that good. We think the bee-keepers owe brother Doolittle a vote of thanks for what he has given to the bee-keeping world; and he does it in a good way, not claiming all the credit himself. That is what I like about it.

Buffalo, Jan. 17. McKINLEY & CO.

WHY THEY CUT DOWN THE COMBS.

What is the cause of the bees cutting down the combs in the surplus chamber in using queen-excluders for extrateting? What is the remedy? S. F. MILLER.

N. Manchester, Ind., Feb. 2.

[We can suggest no cause unless you have spaced your combs closer than 1⅜ or closer than your custom. The queen-excluders could have no influence on the matter.]

IN WHAT CLASS OF THE ALBANY GRADING WOULD SOUTHERN POPLAR OR TULIP HONEY COME?

I see from the reports of the convention recently held at Albany, that there was adopted a standard of grading honey; and from the way I understand the matter, I think our class of honey is left out. Our honey is mostly from the poplar, or tulip; is of good flavor, and amber in color. We have some honey-dew, but we don't put it on the market. If I have not misconstrued the meaning of the report adopted, I could not tell what class to put my honey in. I should like to have a little more light on the subject. L. B. TOLAN.

Kerrville, Tenn., Feb. 8.

HOW LONG MAY A COLONY LIVE?

The folks here tell me there is a swarm of bees near here that has never swarmed, to their knowledge. Can you tell me the reason why they do not? How long will as warm of bees live? L. OZMUN.

PeEll, Wash., Jan. 15.

[A colony of bees may exist for fifty years or longer. In garrets they have been known to live for many years without swarming. But it should be understood that the individual bees and queens live no longer than the average—the continuance of the colony depending upon the infusion of new blood.]

TWO POOR SEASONS, BUT NOT DISCOURAGED.

I am largely dependent on my bees for an income. We have had two flat failures in succession—*no* honey last year, and only two or three pounds per colony the year before, and a heavy feed-bill to foot; but I am not discouraged, and I think I score a point when I say that we need to keep posted more now than ever.

Monroe, Ia., Jan. 12. J. A. MASH.

GOOD WINTERING.

My bees had a fine flight to-day. They bring in a good deal of pollen. They have a good supply of food—no winter loss. They wintered outdoors in my own hives. Many of my hives have no frames in the lower or brood story. I have a movable rack in the top of the lower story, with spaced joists to fasten strips.

O'Quinn, Texas, Feb. 2. J. C. MELCHER.

A GOOD YIELD FOR INDIAN TERRITORY.

My crop of honey for 1891 was 3650 lbs. from 92 colonies, spring count; 3150 lbs. of comb honey, and 500 lbs. extracted, from unfinished sections. I increased to 105 colonies—an average of 70 lbs. per colony. My best hive yielded 157 lbs., all comb honey. This crop of honey brought me a little over $500. M. HERMAN.

Berwyn, Ind. Ter., Jan. 25.

A GOOD INVESTMENT.

I have had only two years of experience in bee culture, and it has been both a pleasure and profit. I began two years ago with four hives, which cost me ten dollars. They gave me 200 lbs. of nice comb honey, worth $20.00. My increase was two swarms. I could see a net profit in the small purchase of $15.00, so last spring I bought quite a lot of colonies which yielded as well as the first. I now have increased my stock to 104 hives.

W. M. SCRUGGS.

Tracy City, Tenn., Jan. 1, 1892.

SOME HEAVY SHIPMENTS OF HONEY.

Mr. E. R. Root:—Your father desired me to send you a statement of the amount of honey shipped by our association last year. We shipped 157,700 lbs. extracted honey, 189,240 net; 28,600 lbs. comb honey, 20,602 net; eight carloads; two went to New York, the rest to Chicago. J. A. R. IRVINE.

Phœnix, Arizona, Feb. 16.

NOTES OF TRAVEL

FROM A. I. ROOT.

AMONG THE BEE-KEEPERS IN THE MOUNTAINS.

As we were standing on the porch at friend Mercer's, talking about it, what should friend M. see but an ocean steamer? She was to leave at half-past ten, and so we had to hustle. I was told the Methodist minister and wife wanted to meet me, even if for only a very few minutes, so we had a little talk; but I hardly felt satisfied, and it seemed they didn't either, for they came after us down to the wharf. Friend Mercer and his wife had consented to go too, and we four got the minister and his wife on board, sent back word to their friends, and took them with us, just as they were. The Rev. Mr. Pettinger, of Ventura, has a strange history. When he was a young man, during the days of the rebellion, he, with about twenty others, captured a train in the South, and attempted to run it up into our lines. So many freight and other kinds of trains were in the way, however, that they got only about a hundred miles. They were taken, and eight of their number were put to death at once. The remaining twelve or fourteen, with death right before them, went down on their knees and made their peace with God as best they could under such circumstances. At this crisis our government interfered and succeeded in stopping the executions, and friend P. finally made his escape. Well, how did all this "death-bed repentance" turn out? I am *very* glad to say that the most of them lived good pure Christian lives ever after; and friend P., after that experience, gave his life to the ministry. Now, please don't scoff or laugh at this, any of you. These twenty or more young men had volunteered to give their lives in the service of their country. Nay, more: like the man who undertook to blow up the iron-clad gunboat belonging to the South, they volunteered a task that was almost *sure* death. They were men of no ordinary courage and bravery. *Such* men, when they dropped on their knees together, and said, "Lord, have mercy on *me* a sinner," meant, as a rule, what they said, death or no death, and so it turned out. I wonder how often they remember that solemn and *awful* little prayer-meeting. Do they sometimes have a reunion and talk it over? Very likely this printed page will meet the eye of one or more of them, for GLEANINGS is now read further and wider than many of us know. If I am correct, every one of that *fourteen* knelt and prayed. *You*, my friend, have probably, at *some* time in your life, promised God, in a similar way, to be *good* and *true*. Have you kept that promise?

Well, that boat-ride to Santa Barbara was one long to be remembered. For the first time we saw pelicans in their native state. They were so wild, however, it was only by the aid of a glass that we could get a view of their strange "dinner-basket," as some one called it—the appendage, or sack, that hangs from the under side of the bill. The bird is about as large as a good-sized goose, with long wide-spreading wings. We also saw the wonderful marine plant called kelp, or giant seaweed. The root is something like a great onion; and the trunk, with its bushy foliage, is like a great tree. As it grows in water from 12 to 20 feet deep, it is a plant of no small dimensions. As it reaches the surface, long branches, or leaf-stems, extend out in every direction, some of them almost or quite 20 feet long. Thus each plant covers an immense surface. Sometimes the foliage is of a beautiful rich red, not unlike the colors of autumn leaves.

The mayor of Santa Barbara was very sick with the grip, and our time was too limited to reach any of the other bee friends, so we visited the old museum there, and took the cars back. This museum is still kept up, and veritable "monks" of olden time have it in charge. The most of them neither see any one of the outside world, nor are they to be seen. Visitors are permitted to go into one small room, and they can also go into the church. Some of the old paintings in the church are very fine, and probably quite valuable. They would be very helpful in our modern Sunday-schools and Bible-teaching, and perhaps they are used in some similar way—we hope so. I do hope, however, that the idea that any human being can be a better Christian by being kept out of sight, and *away* from humanity, may soon be unknown in any clime. "I pray not that thou shouldest take them out of the world, but that thou shouldest keep them from the evil."

J. G. COREY.

Our older readers will remember the story of the cold-blast smoker, and the part that friend Corey, of Santa Paula, had to do with it. We stayed with him over night, and he gave us many valuable facts in regard to the introduction of Italian bees into California. In 1859 he paid $100 for a single colony, and then carried them *on foot one hundred miles*, and walked on snow-shoes to do it. He made a light case, to hold just combs enough to take bees and stores (only 30 lbs.), and strapped it on his back. As he had been employed by an express company to carry express in this way, he was, as it were, trained for the job. Very likely a bee-keeper's enthusiasm helped him to carry out his scheme. His bees lived, and he sold enough of the increase, the first season, to amount to $600. He tried to buy bees of Mr. Harbison, to get a start, but Mr. H. wanted $150 per colony. Before we find fault with these prices, we must remember what it cost to get bees, before there were any railroads. Of course, bee-keepers had a bonanza for a while, raising queens, and increasing, for they could do it almost every month in the year, if they wanted to.

Santa Paula is the oil city of Ventura County. The oil comes from the mountains in pipes, and is here refined. As a consequence they have immense tanks and quite extensive buildings, with the necessary refining machinery. They have just commenced the manufacture of printing-ink, from lampblack and oil, both made from the products of the refineries. Here I for the first time saw a gas-engine, run by gasoline. A certain amount of gas, generated from gasoline, is exploded inside the cylinder, and this gives the power. A small engine was running a machine-shop and other machinery. No governor was used, more than a very heavy fly-wheel, to equalize the force given out by each explosion.

From Fillmore station we reach the bee-ranch of friend McIntyre, that has been recently illustrated and described on these pages. It reminded me again and again of T. B. Terry, while I looked over the ranch and talked with our enterprising friend. Like Terry, and like H. A. March, he pays for every thing as he goes along; and if he can't pay for it, he doesn't have it. He owes nobody, and has something ahead to enable him to grasp good chances when they come his way. Many of the bee-men of California can not have their bees and their families in the same place, and this is indeed a serious drawback. The best places for bees are away back in the mountains, where there are no schools for the children, and where their wives are so far from neighbors and from society it is not pleasant for them. Friend M., however, got his ground *before* the fruit-men; and if they do come into his neighborhood, they can not very well presume to drive him out. Besides, he is a fruit-man himself, and he has orange-trees that he estimates will give him $10 per tree in fruit this year. He also raises young orange-trees. These, when budded, bring from 50 cents to $1.50 each. Three years ago I was absolutely astonished at the prices paid for these trees; and although thousands upon thousands have been raised, the price for good trees remains much the same. It is the old story over again. Friend M. gets wonderful results from only a small part of an acre of seedling orange-trees. His neighbors, seeing how he is making money at it, try to do the same thing themselves, but they have bad luck — the trees die, etc. You see, he prepares the ground so thoroughly, and watches the trees so closely, they *can't* die. The great mass of humanity *will not* pay the price (in diligence and attention) of success. Reader, are *you* letting property go to waste in just this way? May be your wife or your mother can point out just *where* it is. I saw the little water-motor that does their washing, and which is to carry the honey-extractor the coming season. Then friend M. took us up into the canyon, where the oil-wells are located that furnish a part of the oil for the pipe-line that leads to Santa Paula. The wells in California are mostly located up in the mountains, and the oil comes from a peculiar oil-bearing rock. While the quantity is not equal to the wells of the East, it is found nearer the surface, few of the wells being more than 500 to 600 feet deep. We found a single engine pumping four wells, and one engineer looking after all. This engine gives a vibration to something like an old-fashioned horsepower. Each arm works a wire leading to one of the distant wells. Each well has two wires; and these two wires, one and then the other, pulling alternately, work a walking-beam that does the pumping. The tools for drilling are exactly like those used in the East; and, in fact, I found both men and tools had been brought from Pennsylvania. They seemed quite glad to meet visitors, and quite willing to talk; and I do not wonder that they sometimes get lonely away up among these rocky fastnesses. We next went away up into another canyon to a wild, fearful-looking place called the Devil's Gate. Rocks, all the way from the size of an egg up to a fair-sized meeting-house, were so thick in the bed of the mountain stream that it was really frightful climbing up among them. Lest we might indulge in reckless leaping from one to the other, friend M. showed where a man slipped and fell, a few years ago, and lost his life. As no one could find his friends or relatives, nor even his name, for that matter, he was buried on a little bank beneath a branching live-oak. The stones, big and little, have been tumbled and rolled by the water for so many ages that most of them are beautifully rounded and polished; hence it is all the more risky clambering among them. In places the water comes down so steep that it is really a succession of rapids. The water of these mountain streams is usually beautifully clear, pure, and cool; and although I indulge again and again in copious draughts, it never harms me so long as I am exercising in the mountains. Mrs. Root followed as long as her strength held out, and then she rested "under the shadow of a rock" until we came back; but, *didn't* we do justice to Mrs. McIntyre's good bread, and table *full* of good things when we got back!

After dinner our host took us over to see his neighbor, "Tommy Irondale." His name is *Arundel;* but the bee-men think the former is easier to remember and pronounce, and, possibly, a little more stylish. Friend A., as some of you may remember, has solved the problem of being with his wife and children by locating his apiary away up in the mountains where no fruit-men will be likely to want to locate. He has made a road up through the canyon, at his own expense, that is so winding (both up and down as well as sidewise) that Mrs. Root said, just before Mr. McIntyre crossed the stream with his horse and buggy the *eleventh* time:

"If Mr. Irondale had asked *me* to become his wife, with a view of living away up here, I think I should have said 'no' very decidedly."

Now, she did not expect me tell this, of course; but when we all got around the breakfast-table it occurred to me that it was too good to keep, and so I told it, even if Mr. A. and Mrs. Root did look a good deal confused. Well, it helped us all to become acquainted, any way; and when I announced at dinner, that, after Mrs. Root had seen the wonderful view of the valley from the fields above the house, she had changed her mind, and concluded she would not have said "no" after all, she accused me of willful and deliberate false statements. Now, she certainly *did* say she "wouldn't mind living up there *very* much, after all;" and I am going to leave it to the readers of GLEANINGS to say whether it doesn't amount to the same thing.

Friend A. has certainly a very pretty farm up there in the mountain-tops, and his horses seem to have learned the knack of moving great loads either up or down very steep places. The children (five in number) certainly do have a long way to go to school; but, my dear friend, look about you and see if the greatest men have not, as a *rule*, lived out in the country several miles from school. I wanted to add, right here, that *I* lived two miles and a half from the schoolhouse; but Mrs. Root declares *most positively* that I must not say a word about it. You see, she is "sort of" looking after me since I have been sick. Mrs. Root and I decided that Mrs. McIntyre made about the *best* bread in the world; but after we climbed the mountains, and went up the canyon to the falls, we began to think that Mrs. Arundel was fully her equal; and when I began to try to express it, her husband, in his own quaint, comic way, said:

"Lives there a man with soul so dead
Who never to himself hath said,
This is my own, my dear wife's bread?"

I suppose most of you know that the bee-men of our land are, as a rule, a little brighter, more go-ahead, and more respectable than the average men of other callings; but of late I am impressed with the fact that bee-keepers' *wives* are capable of standing right up side by side with their husbands. I presume it has been the case for some time back; but, like many other things, we hadn't found it out. Friend McIntyre placed us in position at the falls, "took hold of the crank" himself, and in due time I hope to present you with a Kodak view of the whole thing. By the way, friend M. told his wife he would be back that night; but it got so awful dark before his patient horse had got us there up the mountain, he decided to stay for supper. After supper the moon came up; but there was so much visiting to do that he did not get away; and when he carried us back to the station next day it was afternoon. Mrs. Root was worried for fear that his wife would be uneasy. We got a pleasant letter a day or two after, in which he said his wife didn't worry a bit, for she gave him the credit of "having sense enough to take care of himself."

From Fillmore we went to Piru Station. I wanted to take Mrs. Root up the Piru Valley, for two reasons: First, I wanted to have her see my good friends the Reasoners; and I wanted, also, to drive through David Cook's ranch of 13,000 acres. I didn't know any one in Piru, and there wasn't a livery-stable there. I told Mrs. Root to sit down in the shade and I would hunt up a vehicle. The station agent said he thought I could get one of a Spaniard just over the way. I went to his house, but the young lady I found there only smiled, and signified that she could not talk our language. I thought if she could *smile* in English she could certainly talk it a little; but I had to give it up. Then I found her father; but he couldn't talk English either, so he called his boy to act as interpreter. It was real fun for me to hear the boy's plain, clear English translation of the musical and somewhat romantic Spanish. The Spanish people have always been interesting to me, and they were doubly so that day. I got the directions, or at least thought I did, and started off. Pretty soon something else interesting took my attention, and I lost my way. Did you never notice how weird and strange things look when you are lost? Well, they look doubly so in California. I finally got into a very pretty garden, and found a man cultivating. I told him what I wanted, and he soon rigged me out. Then we talked something like this:

"My friend, I am an entire stranger here, and how do you know I won't run off with your horse and buggy?"

He didn't say much, but I thought he looked as if my question was certainly a reasonable one. It just then occurred to me that it was getting late, and Mrs. Root must be wondering where I was. Just then I espied some bee-hives piled up against a barn.

"If that man over there is a bee-keeper I think he has heard of me and can convince you that I am whom I claim to be—A. I. Root, of Ohio."

You ought to have seen the look of pleasure as he came up to me and put out his hand.

"Mr. Root, it is a great pleasure to me to see one whom I have often longed to see, but certainly never expected to see at my own home."

"Why, how should you, who are not a bee-keeper, know of me?"

"Oh! our pastor, Mr. Pettinger, loaned me a lot of your journals."

"Mr. Pettinger! oh! that reminds me he told me I must be sure to hunt up a man in Piru who raises strawberries all winter. Does he live anywhere near you?"

"Yes, sir, and I am the man; and as you will need to hurry if you go to Mr. Reasoner's and back before train time, I will get your horse ready. While I am doing so, go right out there and help yourself to the berries. If you improve the time you can get back here at six, and we will give you and your wife some strawberries and cream for supper."

Did you ever! We have the Bible promise that "all things shall work together for good to those that love God," and it does seem as if it had been verified over and over since I have been away from home. I do not mean to boast—you know I do not; but it does seem as if my poor feeble exhortations had been blessed, oh so *much* more than any one could have any right to expect! Friend Pettinger took GLEANINGS when he kept no bees, because it taught righteousness as well as bees; and for the same reason he loaned them to one of his flock who loved God and loved flowers as well as strawberries. And here, right before my eyes, was the fruit of it. I ate a good many berries, and then remembered her, and hastily gathered a few in my hands to surprise her. You can't think how delicious they were after my long tramp that hot, dusty (*January*) day. I put the berries on the seat, and drove out into the main road. Then I looked for the depot, but none was in sight. A railroad *depot* is certainly a big thing to lose; but it was certainly gone, and my wife with it; the sun was declining, too, and we had six miles to drive (up a mountain canyon part of the way) and back again. In despair I appealed to some schoolboys, and they told me which way to drive. How could I ever have gotten so far without knowing it? When I gave Mrs. Root the berries she said she watched me across the fields until I vanished away off in the distance. It really seemed too bad to say "how do you do?" and "good-by" in almost the same breath to such nice people as Mr. Reasoner's; but there was no help for it. Mrs. Root was very anxious to know the name of our good horse that took us along so fast; and when Mr. Reasoner's girls caught sight of him they told us very quickly, for they knew "John," and John showed by his looks and actions that he knew them too; and then it transpired that the Pettingers, Reasoners, and Lentons were *all* good friends, not only because they all belong to the same church, but because they love God and his gifts. "*Blest* be the tie that binds." Mr. Lenton succeeds in having fine strawberries all winter, and in getting a good price for them, in exactly the same way Terry, March, McIntyre, and all these others I have been telling you of do it. They study out the required conditions, and then go to work with all their brain and muscle to secure these conditions. Mr. S. Lenton, of Piru, Ventura Co., Cal., is a florist; but his specialty is just one particular flower, the carnation. In fact, he has a circular, or price list, of new seedling carnations—nothing else. He gave Mrs. Root a bouquet of these that were just wonderful.

What would you think to see "pinks" as large as roses? In his circular he mentions them "three and four inches in diameter." I believe the very large ones are inclined to burst. Now, then, if you are an admirer of pinks I have perhaps done you a service, as well as one to friend L. There is quite a pretty family of them, both boys and girls; and as one boy has a Kodak, and his sister paints in colors, I do not see why our friend should not have his favorite flowers illustrated.

It was dark when we drove into the town of Piru, and we were in another dilemma. I did not take any more "landmarks" when I left Mr. Lenton's than I did when I left the depot. It was almost six, and the strawberries and cream were doubtless ready and waiting. Finally Sue (that's Mrs. Root) suggested that "John" knew where he lived, and so I gave him a loose rein. He seemed a little surprised at first, then seemed to take in the state of affairs; and didn't he just "fly" through the streets! Sometimes he seemed a little undecided, looking up this way and that, with his ears pricked up; and he made so many turns we really began to fear that he like ourselves did not know where he was going; and when he went right past the place which *I* thought was right, we felt more troubled. Finally, however, he wheeled suddenly into the well-known gap in the beautiful evergreen fence, and there we were in good time, right in the midst of friends who were waiting for us. Sue persisted in thinking we must be intruding; but when she found that these good people were, like herself, from "Merrie England," and not very long ago either, it was almost like a family reunion.

And now about David Cook's ranch that I described three years ago. Well, many of the acres and acres of fruit are doing finely, and some fair crops have been harvested already; but it transpired that a good deal of it was planted on ground not suited for it, and some kinds of trees have, I believe, been dug up, and something more suitable put in their place. Large numbers of men and teams are still at work; and the very pretty town and station, with its school and church, are the result of his venture. I feel quite sure that most of such schemes, started *at once*, on such a large scale, *must* turn out a mistake,—much of it. Try a little patch first; then an acre; then five acres; and, if you make a success each season, then it may do to put thirty or forty acres into one crop; but even so fast is risky. Because your *neighbor* has succeeded, it is by no means sure that *you* will succeed. Look about you and see if I am not right. Another thing, don't go and raise a great lot of any thing until you know just where you are going to sell it, and what you will probably get for it. Again, look out that the expense of starting does not eat up all the profits for years to come. A brother of mine went into pigs largely, and made a success of it the first year, to all appearances; but he has a great deal invested in pens that are of little or no value unless he continues in the business. Another thing, his pigs, without a close supervision that he and his family feel they can not undertake another year, are a great nuisance to the neighbors. Of course he could, at great expense, make a pig-proof fence around his ranch; but the business would not warrant this. I suggested making a good fence around smaller limits; but he says experience and all the swine-journals say this will not do. When he started he very wisely got the books and journals pertaining to the industry. These class-journals, if well studied, will save one from useless and expensive mistakes.

Our friend J. J. Cole, of Tropico, near Los Angeles, came here about three years ago. He is the man who bought an apiary where they run water down from the mountain in cane fish-poles. I mentioned it three years ago. Friend Cole went in pretty heavy on the start; but he has had one good season in three years, and this paid him back all he had invested. One part of his apiary is made up of bees that came to him. Last season he secured 32 such; and the year before, 37. This seems astounding, and it indicates that vast numbers of bees must be domiciled in the rocks, trees, ground, and bushes, away back in the great unused fields for honey, in the inaccessible mountains. Friend Corey showed me quite a respectable apiary made up of bees his wife had caught right there in town. They are not only quite plentiful in the swarming season, but in the fall, after a poor year, it seems a good many after-swarms are starved out, for friend Cole got most of his during the months of August and September. Our good honest friend told in the convention of how many bees had come to him and gone into empty hives in his apiary, and the number was so great that our good friend Prof. Cook (not being acquainted with California) created a good deal of merriment by asking whether these bees came to him in the "*night*" or in the "*daytime*."

Mrs. Root says if I am to start a bee-ranch in California it must be at Tropico. Her principal reason is, they have soft spring water, brought down from the mountain. At home we always have cistern water to wash with, *of course;* but here such a thing as a cistern is unknown; and, no matter how hard the water is from the waterworks, everybody uses it for every thing. I have seen only one cistern in the State, and it belongs to my brother. He catches water enough in the winter to last him all summer, and they have one orange-tree full of fruit, irrigated entirely from this cistern.

Friend Cole contributes a tobacco experience. He lost his appetite, and could not eat, either breakfast or supper. Pretty soon he could not eat at *dinner* time either. It was right during the busy time with his bees, and he was fast breaking down. His son's wife, with whom he stayed when working with the bees, worried because she feared her *cooking* was not equal to that of her mother-in-law. Finally a Christian woman, one of the W. C. T. U., I think, suggested that the whole trouble was *tobacco*. C. is a man of sense, and, instead of getting mad because some one told him the plain truth, he *tried* it. Presto! His appetite came back, he fleshed up, and now he is getting *young* again. He said it was a hard fight; but when it was as plain as the nose on a man's face, who wouldn't fight the demon? My own father had a similar experience. He had his youth renewed, after he had used tobacco for more than than thirty years. Now, I wish I could leave my tobacco-story right here; but I am afraid I can not, if I am fair and truthful. Friend C. gave up smoking—chopped it right square off; but he chews yet—"just a leetle." He says he *can* quit that too if he has a mind to, but yet he doesn't. He is a Methodist, one of the good old-fashioned kind, and he knows he *ought* to quit. Shall we not pray that the Holy Spirit from on high may give him grace to shoulder this cross? He is the man, you may remember, who told the company who wanted his farm, to build on it a great distillery, that they couldn't have it for any amount of money, even if he were poor and badly in debt; and when they urged and tried to tempt him he said, "Get thee behind me, Satan," and he stuck to it, even though it cost him something like a *couple of thousand*. He was a *hero* when it came to "*conscience or money;*" but a little pinch of tobacco is a stumbling-block.

GLEANINGS IN BEE CULTURE

Illustrated Semi-Monthly
36 Pages 7×10
$1.00 Per Year

In the multitude of counselors there is safety.—Pr. 11: 14.

At last accounts Mr. and Mrs. A. I. Root were in New Orleans, and expected to visit Florida. They think it will be impossible for them to go to Cuba. At New Orleans Mr. Root had one or two slight attacks of chills; but we hope the trouble will not be permanent.

A LARGE amount of correspondence which we are unable to print furnishes plenty of evidence to show that sealed covers, no upward ventilation, and large entrances, are essentials for successful outdoor wintering. Few if any argue for absorbents and upward ventilation. The fact that the straws all blow the same way is suggestive.

IT has been rumored, though we are unable to get hold of the exact information, that a certain Canadian association of bee-keepers declared that the Porter bee-escape was objectionable in that it tore the wings of the bees. We can hardly see how this is possible, but yet we should like information, either from the Canadians or any one else in a position to know.

A FEW days ago a letter came to hand, bringing the sad intelligence of the death of Mr. Earle Clickinger, the well-know commission merchant of Columbus. As, no doubt, many bee-keepers have sent him consignments of honey, we are requested to announce that all his affairs will be satisfactorily settled as soon as possible. Mr. Clickinger died quite suddenly when away from home on a business-trip.

As evidence of the way fixed frames are being selected, our superintendent, Mr. Warner, informs us that we are now turning out 5000 Hoffman frames every day. This rate has been maintained ever since the first of January. Prior to that we were making 3000 a day, and the demand seems to be increasing. At present, fixed frames are outselling the loose ones ten to one. This shows that bee-keepers who have tested the fixed frames for a year or so back like them.

JUST as we received notice of the discontinuance of friend Andreu's enterprising sheet, Vol. I. No. 1 of *El Colmenero Espanol* (The Spanish Apiary) comes to our table, published by Enrique de Mercader-Belloch, at Barcelona, Spain. It has 16 pages the size of these, very nicely printed. As indicative of the hold that modern apiculture has already obtained on the minds of the Spanish people, we quote the following:

> Bees should be kept only in modern or frame hives—the only ones which, according to our mind, should be employed in the production of honey.

The appearance of this journal is a sign in the right direction, and we are glad to place it on our list of valued exchanges.

WE had a very pleasant visit from Dr. C. C. Miller. On the day of his arrival, Feb. 12, we were just recovering from a severe attack of earache and grip, and fortunately he came just in time to help us out in our editorial work just as the last forms of the Feburary number were nearly ready to go to press. He was very much pleased and interested in some of the new developemnts at the Home of the Honey-bees, and especially admired the principle of the Cowan extractor. While here he suggested a new wrinkle. He showed how we could make this machine *extract both sides of the combs without stopping the extractor*—no, not even so much as reversing the crank. If he was awkward with the Daisy foundation-fastener (see Straws, this issue), he was very expert in manipulating the Cowan reversible extractor on the new idea. He was the first to discover it, so far as we know, and we will let him tell how it is done, himself.

A QUEEN-BREEDER asks our advice as to whether it will pay him to advertise tested queens at $1.25 and untested at $1.00. It is impossible to answer this question by yes or no, as the success or failure of such advertising depends upon several conditions. The queen-breeder who advertises queens must advertise continuously in order that the bee-keeping public may become familiar with his name; and he must do exactly as he agrees. Of all things most ruinous to a queen-breeder's business, it is to take the cash for an order, and then send a queen a month or even longer after the queen is ordered. When a bee-keeper incloses cash for a queen during the later spring and early summer months, he has a good right to expect her to be sent by return mail. When a man suddenly discovers a hive is queenless, it may be a great loss to him to have to wait a week and sometimes a month for his queen. If any of our advertisers delay their customers in this way we should like to be informed of it.

WE are able to publish only a few of the many articles sent in on the subject of bounty versus no bounty on honey. We should be glad to give insertion to them all if we had the space, but we fear so many might be wearisome to the readers. Perhaps we can give the gist of the whole discussion in a nutshell. The decision seems to be almost unanimous that a bounty on honey is not desirable, even if feasible; that bounties in general at best favor only a few at the expense of the masses. One correspondent says, "A bounty on honey is all nonsense, and you just waste ink and labor in having it discussed in GLEANINGS. There are a hundred industries needing and deserving a bounty just as much as honey." The correspondent does not add, but we suppose it is implied, that, if we grant a bounty on every thing, our people would be in a bad plight indeed. For the present, at least, we shall have to cut off all further discussion on the subject, as we are sure that the few articles we have already given sufficiently indicate the general feeling.

IT has been darkly hinted by one or two correspondents that we have rejected communications, either because they were at variance with some of our "pet ideas," or because there was a prospect of their cutting off our bread and butter. Editors may be biased in their opinions; we may be, but we certainly do not desire or intend to be. We have often taken pains to give special prominence to certain sides of discussion that were contrary to our beliefs and experience; and we think that the pages of our journal will carry us out in this assertion. If we suppress communications because they happen to differ from our views, we are unconscious of it. As we said in the *Bee-keepers' Review*, we say now, "sail into" the editor if you think he is giving currency to or is encouraging wrong ideas; but do it kindly. We desire above all things that GLEANINGS shall be unbiased and fair on all subjects. We are sometimes obliged to leave out matter simply because of some peculiar condition or circumstance. One of these conditions may be lack of room; and then there may be a dozen or so good articles, all discussing the same phase of the subject. Manifestly, it would be unnecessary to publish them all.

In the *Canadian Bee Journal* of Feb. 9, Mr. R. McKnight replies to our editorial regarding the matter of non-affiliation on the part of the O. B. K. A. with the N. A. B. K. A. We are pleased to observe a friendly and courteous spirit on the part of Mr. McKnight; for, as he truly says, "The friction is between bodies corporate, and not between individuals." If we can not agree to agree, let us agree to disagree as brothers. Mr. M. adds, further, that he hopes the N. A. B. K. A. is elastic enough to allow him to still remain a member, and we think it surely is. In the same way, we have no doubt that the O. B. K. A. is elastic enough to admit to membership a bee-keeper from the United States. We firmly believe that further discussion is ill advised and unwise, and that it is best to let the matter drop.

SUGAR-FED COMB HONEY.

In the *Bee-keepers' Review*, page 318, Dec. 10, appears an article from Emerson E. Hasty. Said article raises a question as to whether we may not, in poor seasons, when natural sources fail us, feed sugar syrup to our bees to produce comb honey; and while Mr. Hasty does not for a moment advise selling such honey as pure clover or pure basswood, he thinks that, *if* sugar-fed comb honey can be produced at a profit, and sold for what *it is*—that is, cane-sugar honey, there is no special harm done. So far we agree with Mr. Hasty. But the great trouble is, not all the world is as conscientious and honest as is our friend from Richards, Ohio. If such were the case there would be no danger in raising the question. But, unfortunately, there are bad men in the world who might take the knowledge gained by Mr. Hasty's article and make a bad use of it. And, again, if bee-keepers were to buy sugar syrup, stating that they were to use it to feed for comb honey, the newspapers would pretty likely get hold of it and herald forth that bee-keepers were making a general practice of this sort of thing, and were selling it for pure comb honey, even if the bee-keeper *intended* to sell it for cane-sugar comb honey. It is a good maxim to avoid the appearance of evil, so long as we have nothing definite to prove that sugar-cane comb honey can be produced at a profit, and we somewhat question it.* It is not always best to have truth come out. For instance, it might be argued that it would be very unwise for any periodical to publish how to make dynamite bombs, giving all the necessary details for their manufacture. If the people of the world were all honest, no harm would result from the publication of such matter; but, unfortunately, again, there are evil men who might, with the knowledge thus so easily obtained, do great mischief.

While we are compelled to believe the publication of the article relative to sugar-cane comb honey was a mistake, we do not for a moment question the motives or intentions, either of Mr. Hasty or our friend the editor, Mr. Hutchinson. In fact, *no one* can question the intentions of either; and perhaps, under the circumstances, the less said about it the better. The article may do more harm since it appears in a first-class, neatly printed and well-edited bee-journal—one that does honor and credit to our bee-literature, and because the writer, Mr. Hasty, stands high as a contributor and correspondent—one whose writings are invariably spiced with good humor and wit. For instance, right before us is a letter from a subscriber, who, having read Mr. Hasty's article, proposes in all seriousness to feed his bees cane sugar to secure comb honey, as the natural sources have failed him for several years. He does not say whether he will sell it for what it is or for strictly bee-comb honey. This same writer says further, that heretofore he regarded the practice as unprofitable; but if it can be made to pay, as hinted by Mr. Hasty, he is going to "make" that kind of honey. This man is honest enough to admit it; but are there not some others who would produce the cane-sugar honey and keep still about it?

ADULTERATING EXTRACTED HONEY, AND TO WHAT EXTENT THE PRACTICE EXISTS.

For some weeks back we have been investigating to what extent extracted honey is being adulterated on the markets; and while we were loth to believe at first that it was done to any appreciable extent, we are compelled to acknowledge, from the evidence in hand, that there is probably at least some of it done by a few disreputable packing-houses; but we have no reason to suppose that it is practiced to the extent of "hundreds of tons," as first announced. The shameful thing about it is, that one or two wholesale grocery establishments (see Baldridge's article elsewhere) are offering two lines of goods—one adulterated and the other pure. The traveling salesman will offer to the trade adulterated honey, put up in glass packages, at a price considerably below what the same package can be supplied filled with the pure article, and the groceryman is given his choice. They both *look* equally showy, and both taste well, and some grocerymen will buy the adulterated because it is cheaper, and sell it for "strictly pure." Fortunately this barefaced dishonesty is not practiced to any great extent, because the traveling men themselves "give the whole thing away."

There is another class of mixers who sell only adulterated goods, and yet label them "Strictly Pure Clover Honey." We have samples of the latter goods sent us, and the glucose flavor is unmistakable and prominent, and Dr. Miller; who was with us agrees. The packages in question were made up of jelly-tumblers and bottles. Each package contained a small piece of genuine broken-comb honey, and around it is poured a glucose mixture. By way of parenthesis right here, it may be well to warn the public against buying jars of honey (?) containing a piece of comb in it. The latter is probably only a snare and a delusion, and is intended to give the package the *appearance* of honesty. We do not believe there is a single bee-keeper who puts up broken-comb honey in this style—that is, we mean pure honey without any glucose adulteration; and we would warn consumers against buying honey (?) containing a piece of comb labeled with the name of some big city packing-house.

Now, Gleanings does not propose to stand idly by and do nothing about it. Just at present it is not pertinent or wise to make known our plans. But before we get through we will try hard to make some one squirm.

Now, it may perhaps seem a little unwise to come out with the knowledge that extracted honey may be adulterated. Heretofore we had not believed (and the evidence at hand was not sufficient to convince us) that extracted honey could be adulterated at a profit. If it is adulterated, and it surely is to some extent, it is unwise to keep still and let it go on, for that would only give license to evil men, and allow the evil to spread.

---

* Mr. A. F. Unterkircher (see page 101, Gleanings for '86) in feeding back to produce comb honey, out of 3500 lbs. so fed received only 1250 lbs. of fed comb honey. At this rate, sugar-fed comb honey would not pay at 11 cts. per lb.

SPECIAL NOTICES.

PEAVINE, OR MAMMOTH, CLOVER SEED.

The price of this seed has been on the upward move of late. Next to alsike and white clover the bees gather honey from this variety most readily. We have some choice seed, in limited quantity, as follows: 1 lb., 15 c.; 1 peck, $1.90; ½ bushel, $3.60; 1 bushel, $7.00; 2 bushels, $13.00, bags included. By mail, 9 c. per lb. extra.

PLANET JR. GARDEN IMPLEMENTS.

The season for gardening operations is at hand, and these operations are greatly facilitated by the proper tools. The Planet Jr. garden implements have a world-wide reputation. If you are interested in examining the neat and tasty price list of these tools, we shall be pleased to mail you one, inclosing our special net-price sheet offering the tools at considerably less than list prices. Mailed free on request.

BEESWAX WANTED.

The market in beeswax has toned up quite a little, so that we can offer, till further notice, 27 c per lb. cash, 30 c in trade, for average wax delivered here. Be sure to put your name and address in or on the package when you send us wax, for we are daily receiving it; and unless you are careful to mark your box it gives considerable annoyance. We have had two or three such cases lately. Our selling price will be 32 cents for average, 35 for selected. No change to note in the price of comb foundation.

SWEET CLOVER—MELILOTUS ALBA.

Since the appearance of the article on this variety of clover ,found on page 91, the writer has received numerous inquiries in regard to seed, and writes requesting that we notify our readers that he has no seed to sell, but that we can furnish it. This we are glad to do. It is found in our seed list, quoted as follows: 18 c per lb.; 10 lbs., $1.50; 100 lbs., $12.00. By mail, 9 c per lb. extra. This reminds me that any of our readers interested in vegetable-garden seeds, and plants strawberry-plants, honey-plant seeds, etc., can have our 16-page seed catalogue for a request on a postal giving your address.

COWAN RAPID HONEY-EXTRACTOR.

This machine was illustrated and described in the Jan. 15th number, and is also included in our March 1st catalogue, which is nearly ready for mailing. From tests made we are able to reverse the baskets in this extractor about as rapidly and with as great ease as the Stanley automatic, even though it is not automatic. The reason is, that you do not have to bring the revolving gear to a standstill, and then turn the other way, but you simply slow up the motion sufficiently to throw the baskets over with one hand, one after the other, while you keep the other hand on the crank. It is equipped with the new vertical gear, with crank at side of can, and for two L. frames the price is $12.00. A larger size, with baskets 12 inches wide, for deeper fames or two shallow frames in each basket, $14.00.

THE NEW VERTICAL GEAR FOR EXTRACTORS.

Since the article in the Jan. 15th issue, describing this gear, we have had a number of inquiries in regard to it. We put it on any of our regular extractors for $1.00 each extra. It can not be attached to extractors already sent out, because the top part of the revolving basket stands too high. We are getting up a gear with a humpback cross-arm that can be attached to the old extractors, and will give better wear than the old gear. We hope to tell you more of this in our next issue. We can furnish the vertical gear with cross-arm, as shown in Jan. 15th issue, for 17, 20, 22, 28, and 30 inch cans; 17 and 20 inch, $1.50 each; 22 inch, $2.00; 28 and 30 inch, $2.50 each.

ALSIKE CLOVER SEED.

On page 165 of this number will be found an interesting and instructive article on alsike clover—when and how to sow, and the profits derived, both from seed and the honey produced. Agriculturists are learning of its value as a paying crop to raise, but it looks as if they were very slow in doing so. We have known a number of bee-keepers who interested themselves in explaining and proving to their neighbors the merits of alsike, and furnishing them seed, sometimes at cost, sometimes for less, because of the improved pasturage for his bees. As a rule he has been abundantly repaid for his trouble. I don't remember a time in years when seed has been as high as it has this year; but this should not stand in the way of its being used. The seed is so fine that it does not require more than half the number of pounds per acre than it does of common red or medium clover. We have an extra nice lot of seed which we furnish as follows: By mail, 1 lb., 35 c; 3 lbs. for $1.00. By freight or express, at your expense, 1 lb., 25 c; 4 lbs., $1.00; 1 peck, $2.80; ½ bushel, $5.40; 1 bushel, $10.50; 2 bushels or over, $10.00 per bushel. Bags included in such case.

MAPLE SUGAR AND SYRUP.

The maple-sugar season is here, and the woods are aglow with the fires of the sugar-camp. The toilers in this industry are wending their way from tree to tree, gathering nature's sweet, and reducing it to those delicious sweets that surpass honey itself. Ohio is the home of the maple, and our State has laws so strict that it makes it a serious matter to adulterate the products of the maple-sugar camp; and those within the State who are found daring enough for this nefarious business are few and far between, if, indeed, they exist at all. As a consequence, Ohio syrup and sugar have a national reputation for purity, and, as a further consequence, our sales have greatly increased the past year. The sugar bounty does not apply to maple syrup, and to sugar it is in such shape as to be of no benefit to the ordinary producer. A nice article of syrup brings just as much now since the reduction in price of other sugars as before, and there is not much change in the price of maple sugar. These products have a market of their own, just as much as honey, and a fancy article will bring just as good a price in one as in the other.

There are many thousands of gallons of syrup produced within a radius of 20 miles of Medina, besides large quantities of sugar. To help these producers we have for years been the medium for finding a market for a large part of their product. The first run is just coming to market as this goes to press; and in from one to three weeks we shall, no doubt, be able to supply all demands at the following prices:

Choice syrup in 1-gallon cans, $1.20 per gallon; 10 gallons, $10 50; 20 gallons or more, $1.00 per gallon, well packed, and delivered on board cars here. Maple sugar we offer in three grades: No. 1, extra, at 9c per lb.; No. 2, good, at 8c; and No. 3, fair, at 7c per lb. In 50-lb. lots, ½c per lb. less. In barrel lots of about 300 lbs., 1c per lb. less. Sugar is in cakes of from 2 to 10 lbs. each, mostly 4 to 6 lbs. in a cake.

Maple Sugar and The Sugar-Bush

BY

PROF. A. J. COOK,

AUTHOR OF THE

BEE-KEEPER'S GUIDE, INJURIOUS INSECTS OF MICHIGAN, ETC.

The name of the author is enough of itself to recommend any book to almost any people; but this one on Maple Sugar is written in Prof. Cook's happiest style. It is

PROFUSELY ✶ ILLUSTRATED.

And all the difficult points in regard to making the very best quality of Maple Syrup and Maple Sugar are very fully explained. All recent inventions in apparatus, and methods of making this delicious product of the farm, are fully described.

PRICE: 35 Cts.; by Mail. 38 Cts.

A. I. ROOT, MEDINA, O.

WILL sell my **Barnes Foot-Power Saw** for **$15** cash in advance. Saw in fair running order. Attachments, 1 cut-off saw 6 in. in diameter; 1 rip, 7 in., one 6, one 4; one grooving, 4-in.; 1 emery wheel, 4 in.; 1 cutter-head, ⅜ in.

ROOT'S GOODS FOR THE EAST.

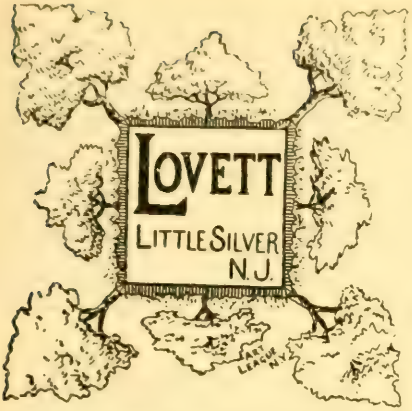
Bee-Keepers of the East should

Bear In Mind that we have established at Syracuse an **Eastern Branch**

where our Bee-keepers' Supplies are kept for sale, and prompt shipment. You can save time and freight by ordering from our Eastern Branch. We have engaged Mr. F. A. Salisbury to take charge of this business, and he will treat you well. He will be pleased to send you a list of goods kept in stock.

Address all orders,

EASTERN BRANCH, F. A. SALISBURY, Agent, Syracuse, N. Y.



TREES and PLANTS that thrive in Northern climates, as well as for Southern. Why not buy direct at half the price usually paid to Tree agents?

Lovett's Guide to Horticulture is issued, of course, with the object of selling goods, but we also bear in mind that the public will not be satisfied to have us blow our own horn unless we take pains to repay them for their trouble in listening.

Hence we have issued this book, which is the most elaborate and complete ever published by any Nursery Establishment in the world. It is finely illustrated and tells all about planting, pruning and care. **Reliable** information fills it from cover to cover. No person interested in the garden and orchard should be without this handsome book. Write for it at once. **It's Free,** or with colored plates ten cents.

CONVENTION NOTICES.

The sixth semi-annual convention of the Missouri State Bee-keepers' Association will be held at Pertle Springs, Warrensburg, Mo., Apr. 6 and 7, 1892, in the parlors of the Minnewawa Hotel — the finest in Johnson Co. A rate of $1.00 per day has been secured for bee-keepers attending the convention.
W. S. DORN BLASER, Sec., Higginsville, Mo.

The Utah Bee-keepers' Association will hold a convention in this city, April 7th. The organization has every indication of being a decided success this time. J. C. SWANER, Sec.
Salt Lake City.

SPECIAL NOTICES.

STRAWBERRIES.

A friend in Indiana calls attention to "strawberries" in our seed catalogue where the *Sterling* is classed as a *staminate* or perfect-blossom variety. The three kinds last mentioned on our list, Sterling, Bubach, and Haverland are pistillates, or imperfect flowering varieties, and need from one-fourth to one-half their number of staminates such as Jessie or Gandy planted with them to insure a paying crop of fruit.

WHITE DUTCH AND SWEET CLOVER SEED WANTED.

Our stock of white Dutch clover seed is almost exhausted, and sweet-clover seed all gone. If any of our readers have seed of either to sell, you will kindly submit samples at once, stating how much you have, and if possible the price you want for it. We withdraw our published selling prices on white Dutch till we are supplied. It will probably be the same price as alsike. We will bill it as low as we can afford on such orders as we receive.

POULTRY NETTING AND FENCING.

Our special netting and fencing catalogue, with discount sheet, is now ready for mailing. These catalogues are furnished us by the manufacturers, and we have been out of them for some months. Owing to enlargement of the factory, and other causes, we have been delayed in getting the lists, and have several hundred applications that have accumulated for the past few months. If any who have already written for one do not receive it within the next ten days, drop us a postal, with another request. We have no change in price to note, our prices being the same as last year, and given in condensed form on page 51 of our catalogue. We shall be pleased to mail the special list to any on application.

MAPLE SUGAR AND SYRUP.

Since the appearance of the notice of sugar and syrup in last number we have received a good many orders, especially for sugar. We have also had a spell of winter weather, so that very little sugar has been brought in yet by the producers, although we have syrup enough offered to meet all demands. We hope very soon to have plenty of sugar for all orders. In former years we have always had a surplus, and see no reason why we should not have enough for all demands this year. As we have three grades of sugar, and syrup is offered us in about as great variety, we have decided to offer you two grades of this. No. 1 gilt-edge will be $1.20 per gallon; 10 gal., $10.50. No. 2, good quality, $1.00 per gallon; 10 gal., $8.50. What we list here as No. 2 good is liked by some fully as well as the gilt-edge, and by some even better. It is a good ordinary run of syrup, and we can supply you all you want at above figures.

NEW HAMMOND TYPEWRITER FOR $60.00.

We have a new Hammond typewriter that has not done two full days' work, that we offer for sixty dollars. It has the "Universal" keyboard, same arrangement as the Remington. We got the machine expecting to use it in our office because of some superior points that it possesses over other machines. We found on trial, however, that, although the arrangement of the keys is the same, the touch of them is so different that a Remington operator could not write successfully on the Hammond without learning over again. The Remington and other similar machines have the staccato (or piano) finger movement, while the Hammond has the legato (or organ) movement. The Hammond seems to be preferred by clergymen and other professional men who do not use it continuously as we do in a business office. Dr. Miller and G. M. Doolittle both use and prefer the Hammond, and would no doubt tell you that the above offer is a bargain.

A GOOD TIME COMING.

As a rule I do not like to hear people grumble; but there is one kind of grumbling that I am watching and waiting for—yes, I am hungering to hear a little of it. When it comes I expect it to be something along in this line: "What has got into these farming people? They are getting so they charge a body just what they have a mind to, and they know we can not help ourselves. Clover seed that used to be three or four dollars a bushel is now eight and ten; and these bee-keepers that raise alsike want even more. The yellow onion-sets are $7.00 a bushel at wholesale. Wheat and flour are going up constantly, and nobody knows what things are coming to." Well, friends, I have not heard anybody say just that; but in looking over a price list dated March 15, of seeds, etc., I thought it looked something like it. There has been, as you know, a tendency to run away from the farms, and crowd into town; and I fully expect that these people who like real progressive farming are going to have a good time after a little. So don't you be in a hurry to desert the farm where you are now doing even tolerably well. A. I. R.

CLOVER SEED.

Two weeks ago we announced an advance in the price of peavine or mammoth clover seed from $6.00 to $7.00 per bushel. It has since gone up at such a rate that it is worth to-day fully as much as alsike, which we are selling at $10.50, or two bushels for $20.00. Common red or medium clover is also the same price. This ought to stimulate the demand for alsike seed, because it does not require more than half as many pounds of seed to the acre as of the large clovers, because the seed is so fine. You can see from the article on page 165 of last issue that it is fully as valuable for hay, as well as for a paying seed crop. We have a good supply of choice seed at prices last named. We can not fill orders after this date for peavine at less than the price of alsike, unless the market subsides again. You may be sure we will give you the best price we can, consistent with the market as it rules at the time your order comes. Some few are so unreasonable as to insist that we fill orders at the catalogue price printed some time ago, no matter where the market goes or what we have to pay. As a rule, these are the people who do not watch the market and inform themselves of what is going on. When the market is so unsteady as it has been on clover for the past two or three months, there is no printed price list that can keep pace with it; and we distinctly state that prices are subject to change without notice. As we have a good supply of alsike we can maintain present price.

DECLINE IN THE PRICES OF GARDEN SEEDS.

In fixing the prices on our seeds we do not wish to be below other reliable seedsmen, neither do we wish to be above them. When we grow a fine stock with much pains and care, we at once consult offers from various reliable sources, and fix our prices accordingly. If we discover later that some reliable grower has given a better price, of course we must adopt the same price, whether we make or lose in the operation. Therefore we make the following changes in our catalogue for 1892. In taking these prices, please remember they are figured so close that, when seeds are wanted by mail, you must add 1 cent per ounce; 5c per half-pound, or 9c per pound, to cover postage and packing. Peas and beans by the pint and quart must also have 8c per pint and 15c per quart added. On corn, add 12c per quart.

NEW PRICES ON GARDEN SEEDS.

Henderson's bush lima bean. Qt., 40c; peck, $2.75.

Kidney wax bean. Pint, 15c; peck, $1.50.

Extra early Jersey pole lima beans. Qt., 30c; pk., $2.:5.

King of the Garden lima. Qt., 35c; peck, $2.25.

Henderson's Early Summer cabbage. Oz., 20c; lb., $2.25.

Fottler's Brunswick. Oz., 20c: lb., $2.00.

Large Red Drumhead. Oz., 20c; lb., $2 25.

Dwarf Golden Heart celery. Oz., 15c; lb., $1.75.

Corn, Corey's Extra Early; Shoepeg; Late Mammoth, and Gold Coin will all be sold at the uniform price of ½ pint, 5c; qt., 15c; peck, 75; bushel, $2.75.

Lettuce, Grand Rapids. Oz., 20c; lb., $2.25.

Muskmelons, Emerald. Oz., 10c; lb., 75.

Miller's Cream, same as above.

Onions, Silverskin, or white Portugal. Oz., 25c; lb., $3.00.

Yellow Globe Danvers. Oz., 20c; lb., $2.00; 5 lbs., $1.75 per lb.

White Victoria. Oz., 25c; lb., $3.00.

Parsnip, Improved Guernsey. Lb., 40c; 10 lbs., $3.00.

Peas, Alaska. Peck, $1.50; bushel, $5.00.

American Wonder. Peck, $1.75; bushel, $6.00.

Stratagem. Qt., 25c; peck, $1.75.

Sandwich Island oyster-plant. Oz., 10c; lb., $1.25.

Squash. Giant Summer Crookneck. Oz., 10c; lb., 65.

Hubbard squash. Oz., 10c; lb., 65.

Tomato. Golden Queen. Oz., 20c; lb., $2.50.

Ignotum. Oz., 25c; lb., $2.50.

Dwarf Champion. Oz., 20c; lb., $2.50.

Turnip. Breadstone. Oz., 10c; lb., 80c.

Those who have purchased since the first of January, and who have paid enough more than the above figures to make it worth while to call our attention to the fact, can have a rebate corresponding to the above, when they make it known. Prices of other seeds will be as in our seed catalogue, which is ready to mail on application. As usual, there are liable to be sudden changes, without notice. As an illustration: Almost every seedsman in the United States has sold out on the Prizetaker onion, therefore the price has gone up so that it would be impossible for us to hold to our printed price list were it not for the fact that our boys got the price pretty well up to start with—$6.00 per lb. Just now the very best figure that can be obtained of William Henry Maule, the originator, even on 10-lb. lots, is $5.00. Thus you see why a seedsman must add, "All prices are subject to sudden advances without notice." The rapid fluctuations on clover seed within a few days (see mention elsewhere) is a vivid illustration of this. Therefore do not get cross and call your seedsman names because he sometimes finds everybody sold out to such an extent that he absolutely *can not* adhere to his printed price list.

COLD-FRAME CABBAGE-PLANTS.

We have three or four thousand of these that we should be glad to dispose of at once, as the room they occupy is wanted for other purposes. Of course, they are the Jersey Wakefield.

STANLEY EXTRACTORS.

We desire to notify those in want of these machines that we are now the manufacturers, having bought out the stock and good will from E. R. Newcomb, and the control of the patent from G. W. Stanley. We have a good stock of machines ready for prompt shipment.

HONEY COLUMN.

CITY MARKETS.

DETROIT. *Honey.*—Comb honey is selling very slowly. Stocks rather low. Best bringing 13. Extracted, 7@8. *Beeswax*, firmer at at 26@27.

M. H. HUNT,
Mar. 9. Bell Branch, Mich.

CINCINNATI. *Honey.* No change in the market since our last. Demand is slow. Extracted honey brings 5@8 on arrival. Comb honey sells at 14@16 for best white in a jobbing way.

Beeswax.—There is a fair demand for this, at 23@25, for good to choice yellow on arrival.

CHAS. F. MUTH,
Mar. 9. Cincinnati, Ohio.

SAINT LOUIS.—*Honey.*—Market very quiet in comb, at unchanged prices. Some inquiry for extracted at 5¾, in barrels; 6½@7 in cans. *Beeswax*, prime, 27.

Mar. 9. D. G. TUTT GRO. CO.,
St. Louis, Mo.

KANSAS CITY.—*Honey.*—The market for all kinds of honey is very slow. The supply is large, demand light. We quote: No. 1 white, 1-lb., 14@15; No. 2, 13@14; No. 1 amber, 1-lb., 10@12; No. 2, dark, 8@10. Extracted, white, 7; amber, 6@6½; dark, 5@5½.

Beeswax, 23@26.

Mar. 9. CLEMONS, MASON & CO.,
Kansas City, Mo.

BOSTON.—*Honey.*—We quote you our honey-market as follows. One pound comb white, 13@14. Extracted, 6@7. Demand fair.

Mar. 9. BLAKE & RIPLEY,
Boston, Mass.

KANSAS CITY.—*Honey.*—Demand poor, with a large supply of comb. We quote: Comb, 1-lb., fancy, 14@15; dark, 8@9. Extracted, white, 7; dark, 5@6. *Beeswax*, none on the market.

Mar. 9. HAMBLIN & BEARSS,
514 Walnut St., Kansas City, Mo.

PORTLAND.—*Honey.*—Comb honey scarce, 1-lb. selling 16@18; 2-lb., 14@16. Extracted, 6¾@7½.

Beeswax, scarce at 30.

Feb. 25. LEVY, SPIEGL & CO.,
Portland, Or.

ALBANY.—*Honey.*—Since the beginning of Lent there has been considerable demand for comb honey, but at reduced prices. The Jewish trade are also beginning to buy extracted for their annual festivities, which occur soon. We quote: White-clover, 11@13; mixed, 9@10; buckwheat, 8@9. Extracted, light, 7@8; dark, 6@7. *Beeswax*, 25@26.

Mar. 10. CHAS. MCCULLOCH & CO.,
Albany, N. Y.

CHICAGO.—*Honey.*—The market is not very active; but some sales are made at unchanged prices. Fancy comb sells at 15@16; off grades and dark comb are uncertain in price. Extracted sells freely, at 6@7@8, according to kind and quality. *Beeswax*, 25@27.

R. A. BURNETT,
Mar. 8. 161 So. Water St., Chicago, Ill.

FOR SALE.—California 2-lb. section comb honey at 12c per lb. Wis. and Mich. 1-lb. section candied comb honey at 11c per lb. If you want honey of any description, write us. S. T. FISH & CO.,
4-5-6d 189 So. Water St., Chicago, Ill.

FOR SALE.—One 30-gal. bbl. medium dark honey, fine flavor, at 5c per lb. One 45 or 50 gal. bbl. of mangrove, very white and candied solid, of fine quality and flavor at 5½ net, f. o. b. Samples sent to intending purchasers, if desired. J. B. CASE,
Port Orange, Volusia Co., Fla.

FOR SALE.—20 lbs. extracted clover honey, in new buckets, for $2. By the barrel cheap.
6-7d B. T. BALDWIN, Marion, Ind.

FOR SALE.—A No. 3 Novice Extractor, used only once. Price $6.00. Freight paid.

My 654 Colonies of Italians

Are wintering well, and, as usual, I will sell a limited number of them to reduce stock to the required number. Each hive shipped to my customers will contain a full prosperous colony of Italian bees, with a last year's tested queen, on eight Hoffman frames of brood and honey. As my main object in handling bees is honey, we raise all our queens in full colonies from cells built under the swarming impulse, using the choicest and most profitable stock to breed from.

Safe arrival guaranteed in May and first half of June. For terms please address

3-8db **JULIUS HOFFMAN,**
CANAJOHARIE, N. Y.

☞In responding to this advertisement mention GLEANINGS.

Good Queens Cheap.

300 tested Italian queens, raised last season, for sale at $1; $10 per doz. A few hybrids at 25c each. They will be shipped about June 15th to 25th, or later if desired. Have order booked now and send money when you want them. My bees have been *BRED FOR BUSINESS*, and these are bargains. Nuclei and full colonies at very low rates. Send 25c for sample by mail of

THE UTILITY BEE-ESCAPE.

Thoroughly tested, practical and cheap. It cleans them out and they stay out. Any one can make it. Get a sample and make your own. 4tfdb

Vol. XX. MARCH 15, 1892. No. 6.

STRAY STRAWS

FROM DR. C. C. MILLER.

I'M OFF THE FENCE with both feet, standing up straight for no bounty.

A WAIL comes from Minnesota, that tent caterpillars are destroying basswood bloom.

MRS. AXTELL says in *P. B. K.* that "it takes brains to care for bees." Just listen to her!

MICA in stoves will soon become dim if you burn any thing but hard coal. No wood, paper, or soft coal.

THE *C. B. J.* thinks it high time something were done about a bee-keepers' convention at the World's Fair.

ADULTERATION exists. Plenty of it. No use to blink the matter. *Fight* is the word. No make-believe fight, either.

REMEMBER that bees consume six times as much honey in April as in December; and if you don't look out some will starve.

EDITOR COOPER, of the *Bee-keepers' Magazine*, is doing missionary work, trying to get people to plant flower-seeds. Success to him.

THE ONTARIO Bee-keepers' Association sends free to each member this year a copy of the *C. B. J.*, the same being a good paper.

ARTIFICIAL HONEY is made in Germany so good that scientific men say it can't be detected. But the bee-men say it tastes like burnt sugar.

ALLEY has 32 colonies in the house-apiary, with the view of getting them strong earlier in the season. In May *Api.* he'll tell how it works.

GOOSEBERRIES, as honey-plants, are recommended to be planted in fence-corners, everywhere, even in waste places, by F. Huck, in *Deutsche Imker*.

COLORADO beats Michigan. L. Brock, at Colorado State convention, said it cost $1\frac{3}{4}$ cents per pound to produce comb honey. Now, who can do it for $1\frac{1}{2}$?

MRS. MILTON CONE (*Api.*) says a flock of Pekin ducks allowed the range of their apiary almost depopulated the hives; but she raised 700 chickens all right.

I SAW A BOOK about patents, on Ernest's desk. Has he so far departed from the way in which he was brought up as to be contemplating the getting-out of a patent? May be he intends to patent sealed covers.

J. B. HALL denies the soft impeachment that he advocates a $\frac{3}{16}$ bee-space. I thought it seemed a pretty tight squeeze; but there it was, in cold print, on page 784, *C. B. J.* Did the *C. B. J.* printer man monkey with those figures?

I DIDN'T BELIEVE G. K. Hubbard was hard-hearted enough to keep that boy standing always working at his section press. The picture now shows him sitting down.

U. GUBLER (*Review*) thinks it probable that, the older the larva, the older the nurse-bee that feeds it, a larva of one or two days being fed by a nurse not more than five days old; a nurse nine days old preparing a suitable diet for larvæ of four or five days.

THE PROGRESSIVE BEE-KEEPER gets a raking from one of its patrons for using type so large that it "is first-reader type, fit only for children to read." Yes; but, friend Urban, you don't know what a comfort to spectacled eyes is that same large type, so beautifully printed on nice paper.

I'D GIVE quite a little to have friends Doolittle and Taylor shut in a room together to argue out the cost of honey—kept there till they agreed—and they would agree if they had time enough—and then have a phonograph report the whole thing. We'd get some valuable points.

THE *C. B. J.* calls the N. A. B. K. A. a stock company, and doubts "if a meeting of stockholders will be as interesting as a convention of members." Say: if I've been fooled into this thing, and we're not to have a convention of members any more, I'm going to get out and join the O. B. K. A.—if they'll let me.

OUTDOOR WINTERING was a success with the four colonies I packed in the winter of 1890. I left out 12 last winter to try in winter cases. Failing to get cases in time, I concluded to leave the 12 out without protection. I wanted to find out how they would winter in that condition. I found out. Just 100 per cent of them died dead.

THE NAME N. A. B. K. A. has too much alphabet in it. R. McKnight, in *C. B. J.*, shortens it to N. A. B. A. That's sensible, especially as "Bee-keepers" is really only one word, and there is no initial K. Wouldn't it be sufficiently distinctive to call it, for short, "North American Association," and use the initials "N. A. A."?

QUIGLEY had bees in hives with flat covers. "After a light snow," he says' "the snow had melted over the cluster on all of them, showing just where they had clustered, while the snow on the covers of empty hives had not begun to melt. Don't you think from the above that some heat escapes through a $\frac{7}{8}$ board?" Yes, and it shows that packing *over* the board would be an improvement.

"I HAVE business relations with some 73 societies, and have become personally acquainted with more than 3000 bee-keepers. Among the 3000 I do not know of one drinker." So said Mr.

Glatow, in the Centralverein of Germany. I think it has been noticeable that, in every body of bee-keepers I have ever seen, they were an exceptionally clean set of men. Mr. Glatow thinks bee-keeping helps to make them so.

THE LAYING OF QUEENS, the German writer Gerstung contends, is not continuous, but periodic, about 7 periods of 22 days each in a season; 16 or 17 days of laying, followed by 5 to 7 days of rest, makes the period of 22 days. I should have said eggs can be found any day in my hives; but if Gerstung is right, there ought to be a day or two every three weeks when there is not an egg in the hive. Let's watch, this summer.

THIN SECTIONS, not more than 1½ thick, have the following strong points claimed in their favor by the *C. B. J.:* Capped sooner than thick ones; whiter, because less time in hive; looks clearer when you look through the sections; honey thicker; ships better; sells better. All right, friend Jones, I'll change to any thickness you say, if you get the rest to agree; but don't, please don't ask us to change from 4¼ for the other dimensions, just as we've settled on that for a standard.

A CORRESPONDENT, referring to the editor's statement that he can get bee-work done for $1.50 to $2.00 per day, thinks emphasis should be placed on the qualifying clause, "*providing we supervise or superintend the work.*" I don't see that there's any thing particularly out of balance in that correspondent's head. If you had a number of hands and hired a superintendent, wouldn't you charge up the superintendent's time in expenses? And shouldn't you charge for your own superintending?

CHEMICAL ANALYSIS made by the U. S. Government chemists, has in some cases decided that honey was adulterated, or "apparently adulterated," which was known to be pure. Perhaps this is the explanation, which I get from the German: In polarization, honey turns to the left, cane sugar to the right. But honey-dew turns to the right also; and as even the finest samples of honey are likely to have just a little honey-dew in them, polarization would show "apparent" adulteration where there was none.

HONEY FOR GRIP is going the rounds of the German dailies. Take daily a teaspoonful of honey and let it dissolve slowly on the tongue, as a preventive, the formic acid killing the bacillus that attacks the mucus membrane of the throat. Honey dissolved in water and drawn into the nostrils hastens a cure. The *Deutsche Imker* adds that, besides being pure, the honey must not have been heated, for that dispels the formic acid. That's all right for a German bacillus; but do you suppose a wide-awake Illinois bacillus would give in for a little thing like that?

COST OF COMB HONEY, AGAIN.

DOOLITTLE REPLIES.

The main part of my mission in this world is to stand for *God*, for the *right*, and for *humanity*. Feeling this to be the case, and feeling that you, Mr. Editor, and Messrs. Taylor and Hilton, are wrong on this matter of the cost of comb honey, I crave the privilege of being heard again on this subject in GLEANINGS. The position you three take savors much of the ideas advocated by the hard-fisted and hard-hearted of this world, that a few should receive a *large* share of this world's goods, while the average person should work for a *mere pittance.* B. Taylor, in his noble article in the February *Review*, says, "In this age, grab-games of one kind and another get away with more than half of all we earn." But according to the three persons named above, it is not "grab-games" which is doing this, but "net profit" is to take nearly the *whole.* I wish it distinctly understood, that Doolittle believes that the labor of *hands* and *brains* is just as much *cost* in producing honey as is the money spent in buying hives, crates, sections, or any of the other cash outlays; also that the labor of hands and brains is just as much *cost* in overseeing the apiary as it is cost in producing manufactured articles or in running any other business of the country, where $1000, $5000, $10,000, or $20,000 is often paid an efficient overseer. Yet, with Mr. Hilton all of this overseeing, and with Mr. Root all of his "supervising or superintending," is to go in as profit. When I was a boy at school, a classmate and myself were called the dullest scholars in the whole school. Doolittle finally went at bee-keeping, and the classmate as a salesman on the road. The classmate receives $2000 a year salary; but, according to Taylor, Doolittle should cost only $45 for six weeks in the year (and that right at the time when the agricultural world pays the highest wages), that he may count all that he receives more than that as profit. If this is right, this classmate should call all he receives over $1.07 a day, profit. In a recent paper I see that a certain company had employed a certain person to superintend their business at a salary of $18,000 a year. Now, shall this man, according to Hilton, Root, and Taylor, count all he receives above $1.07 to $2.00 per day as profit? He cost the firm that amount ($18,000). Would it have been any less cost had the proprietor taken that place and received the $18,000 himself? No! *no!* NO! Let us be reasonable. If Mr. Hilton oversees his workmen and his apiary he is entitled to the worth of his intelligent brains, and that worth is *cost*, just as much as any part of the matter, and he is just as much entitled to good pay as is my classmate or the overseer mentioned above. These things are not *profit*, and it is not right to have it put before the world in that light. Again, when we speak about how much it costs to produce comb honey, we mean the cost with the *average* bee-keeper, if we would be fair, and *not* the cost with those who have exceptionally good facilities for its production cheaply. A man and his son once cut a bee-tree. They were gone from home two hours, and obtained 150 pounds of honey. This honey cost only about ⅓ of a cent a pound. Would it be right for me to say, "This is what it costs to produce a pound of comb honey"? I fancy I hear a tittering all along the line; and yet this is only on a level with Bro. Hilton's figures. What has been done by one, others can do. In looking over "beedom," we find the average man keeping one yard of bees, and this, in the majority of cases, gives the best results. To the care of these bees he devotes all of his energies, except the work usually done in the garden and his small place. If he were a better man he could do more, but he can not be changed; besides, it takes a pretty fair sort of man to do this. This man could get, in some manufacturing town, from two to three dollars a day, and board himself. Say he could get $600 a year; then, as a bee-keeper, he is a six-hundred-dollar man, and that is a part of the cost of producing his crop of honey. To claim otherwise is unworthy of the intelligence of an American citizen. If my classmate had gone into bee-keeping he would be a two-thousand-dollar man, and if he could not get that out of the bees he would go on the road again; and I see no logic that can make any *net profit* to him out of his bees till they pay him more than the $900, besides and above the other necessary expenses. Can you, friend Root? If this is so—and I can see nothing else—then I have a right to the $5.00 a day as the cost of my labor in the bee-yard, if I can secure that much. I have no objections to friend Root's saying I am "getting good pay" (though but a trifle compared with what some get), as he does in his footnotes; but when he says, "or, if you please, profit," I don't please, for that would be saying that I was not worth as much to the world as my equally dull classmate, whom the world considers worth nearly twenty per cent more than that. Of course, our six-hundred-dollar bee-keeper raises something on his place, has his garden, and has his house-rent; but it is usually as cheap to live in a hired house as to keep one in repair, counting interest on money. What he raises on his place is more than offset, with the majority in the country, by its disadvantages, such as the lack of best schools, best churches, and social privileges. Add $600 a year to Hilton's or Taylor's estimate, and their showing will be very different, and very much nearer the truth. We are, or *should be*, talking of what *actually is*, not what might be under the most favorable or ideal conditions. A man running a supply business, a farm, or some other business, may sometimes get his honey cheaper, especially if he allows his other business to pay him the salary he is entitled to; but such would not be a correct and proper showing.

I might mention other things which no one has taken into account so far, such as that, when the bee-keeper dies and his business is sold out, it decreases in value from 50 to 75 per cent, while the average bee-keeper runs his business less than twenty years; change of surplus arrangements, etc., caused by continual improvement, long before they are worn out; buying queen-excluders, bee-escapes, drone-traps, and all of the many things necessary to keep up with the times, which would make the interest nearer twenty per cent than the eight which Bro. Hilton allows. Much more might be said along this cost side, but I forbear. All know that the bee-keepers of our land are *not* getting rich, as far as dollars and cents are concerned; and it seems to me to be a wrong idea to make such a great cry of *profit* where there is so "little wool." G. M. DOOLITTLE.

Borodino, N. Y.

[Now, friend Doolittle, don't you think you are a *leetle* "hard-hearted" in intimating that our position "savors of the hard-fisted"? We agree with nearly all you say, and, it seems to us, you would hardly have produced some of these self-evident arguments if you had taken in the *whole force* of what we three said. Let us throw aside the term where we split, *profit* and *cost*, and look at it this way: You are making a good living if you can get $5.00 per day out of the bees; so are Taylor and Hilton. The fact is, we are in reality on the same platform, only we didn't know it, or perhaps won't admit it. Dr. Miller's article which follows makes this plain.]

COST OF COMB HONEY.

DOOLITTLE'S WAGES VS. TAYLOR'S PROFITS.

Don't expect me to settle the question. I don't know enough. But when three men, possessed of as much intelligence as friends Taylor, Doolittle, and Hilton are so wide apart in their conclusions, it is worth while to inquire into the matter and see whether it is not possible to bring about a reconciliation. I have confidence in the honesty of the three men; and when they give different answers to the same question, it must be they are looking from different points of view.

I wish we had from each of them a statement as to what each means by *profit*. Perhaps all three would agree that profit is the difference between cost and selling price; but they may not all mean the same thing by this. When it comes to defining *cost*, I suspect they are using the word with different meanings. Doolittle says of Taylor, "Is not his time worth just as much in the apiary as it is in the senate or anywhere else?" May be, and may be not. If Mr. Taylor can get $10 per day for his time at the bar or in legislative halls, it does not follow that it is worth the same everywhere else. I can get a man to saw wood for $1.50 per day. If the Hon. R. L. were to saw my wood, I shouldn't like to pay him $10 a day for it, nor $1.50. No, I wouldn't be willing to pay him $1.07. I don't think he's worth it. But I might be very glad to pay him $5 an hour if I needed his valuable advice on some legal point. So I don't believe Mr. Doolittle is right if he wants us to believe that the same man's time is worth the same amount wherever it is placed. I don't believe he meant to have us think so.

A somewhat troublesome friend at my elbow stoutly insists that Doolittle is right. She says that, if he can make $10 every day at his profession, and I want him to stop a day to saw wood for me, I ought not to expect him to do it for less than $10—a putting of the case that I can not well refute.

But I don't see that I'm getting ahead any at reconciling Doolittle's $5 a day with Taylor's $1.07. I think friend Taylor's position is something like this: If I can get a man to do my work at $1.07 per day, then I ought to figure $1.07 as the cost of labor, whether I do the work myself or get some one else to do it. Of course, when I come to sell my honey I expect to get more than it has cost me, else where is there any profit in the business? And I am entitled to a profit on the score of the skill and knowledge I have used in directing the labor?

If I interpret friend Doolittle correctly, he would say: "It requires skilled labor to work at bees; and during the busy season I would not be willing to work for another person for less than $5 per day, neither do I think I could hire any one of equal ability for a less amount. It seems quite clear, therefore, that, $5 per day is a fair amount to figure, in estimating the cost of honey."

Now, when you get down to bedrock is there any real difference in the views of the two men? To compare their real views more fairly, this question might be put to them: At what price will you contract to sell all the honey you raise for the next three or five years? I doubt whether you would find them so very far apart in their answers. However they may talk to each other about the cost, when they come to sell the product, each one wants pay for the same thing, and probably about the same amount of pay. Taylor wants pay for the labor and also for the skill; and Doolittle wants pay for his skilled labor. Where's the difference?

Mr. Doolittle estimates that 6000 lbs. of honey cost $900, or 15 cts. per pound, and consequently there is no profit in it when sold at 15 cts. per pound. Mr. Taylor estimates that 6000 pounds cost $375; therefore when sold at 15 cts. per pound there is a profit of $525. But, mark you, Mr. Taylor makes no charge for skill, and Mr. Doolittle does—that is, he charges for skilled labor, which is skill and labor.

I think the editor gives the key to the situation when he says, on page 120, "When he charges himself $5 per day for labor, and gets that much in return, he is getting good pay; or, if you please, profit." That's it, pay *or* profit. It's a difference of names. Mr. Doolittle gets his *pay* for his skill, and gets no profit. And if he gets a fair price for his skill, he is entitled to no profit. Mr. Taylor makes no charge for his skill, and figures a profit. One calls it *pay*, the other calls it *profit*.

If any one should insist that, in Mr. Taylor's case, there is a net profit of $525 on the 6000 pounds, independent of any skill, I think a little consideration will show him his error. If skill cuts no figure in the case, then Mr. Taylor has nothing to do but to turn his $1.07 man loose in his apiary, and pay no attention to him all summer long. Or, do you suppose Mr. Taylor would spend the time and thought he has spent upon bees, pay for books and periodicals, and going to conventions, with no expectation of getting any pay for it? Will he do it just for the fun of it? No, he likes fun, but he doesn't believe in that kind of fun "that we alone enjoy" without our wives and children having a share in it—unless he gets pay for it.

The question whether it is the right way to charge for skilled labor, and if so, how much, is not easily answered in a word. I have attempted here to show only that, in the item that shows the greatest disagreement, it is a matter of names rather than any thing else.

Marengo, Ill. C. C. MILLER.

[You are quite right, doctor, and we are glad to have you explain it. The whole thing, as we understand it, in a nutshell, is this: Mr. Doolittle figures his profit, or pay, in the amount he charges himself or his apiary for his labor. Mr. Taylor figures in the actual cost of hired labor; and whatever he makes over and above expenses in the production of a crop of honey makes up his profit, and is therefore the pay for his skill in supervising. After all, the two correspondents mean about the same, only they look at it from different standpoints. What one calls "cost," the other divides into cost and profit. We can not help believe, however, but Mr. Taylor's use of terms is correct. Here is another well-written article from Mr. Taylor.]

ECONOMY IN HONEY PRODUCTION.

THE COST OF A POUND OF HONEY; R. L. TAYLOR REPLIES.

In GLEANINGS of Feb. 15th, and also in the *American Bee Journal* of Feb. 18th, I notice that Mr. Doolittle vigorously attacks my address on the above topic, delivered Dec. 31st last, at the meeting of the Michigan State Bee-keepers' Association; and being impressed with the surpassing importance of the subject, I am constrained to examine as briefly as I may, consistently with clearness, the objections he raises to the position I there took, and I shall first refer to his argument in the *American Bee Journal*.

Our critic there cites my partial indorsement of his figures, made four years ago, where I stated he had overlooked the losses in winter and from disease. It is only necessary to reply that I am four years older than I was then. I trust I know more. Besides, I have found and use a hive that very greatly reduces the necessary amount of labor required in the apiary; and as to winter losses, I think I have learned how to reduce them to almost nothing. And then, if it were any sin to grow, it would come with ill grace from him to taunt me with it; for let him compare the statement he made four years ago of the items which go to make up the cost of the production of honey with the one he makes in GLEANINGS now. Of course, he made each of them carefully and conscientiously, according to the light he had at the time. Then he put the time necessary to care for 100 colonies at 313 days; now he puts 81 days, including the time required for the perusal of apicultural books and journals, and for attending bee-keepers' conventions as the time necessary for the care of *150* colonies! Then he put the interest and taxes, and the wear and tear on plant and hives of 100 colonies, at $64; now he puts them at $180 on those of 150 colonies! Now he insists on all owing the apiarist $5.00 per day; then he allowed him but $1.25! So we are in the same skiff. If not dead we are all moving. What should most concern us is, are we moving in the right direction?

Of course, this growing knowledge greatly reduces the cost of the production of honey; but I have never shed tears over the reduction of the cost of any thing useful to humanity. If to assume that attitude "belittles our pursuit," so much the worse for our pursuit; but I feel very sure it can not prevent our rising to the "stature of God's freemen," whatever may be meant by that sonorous phrase. Cotton cloth which once cost 50 cents per yard can now be produced for 5 cents; and if I show that it can be made for the latter sum, I can not see very clearly how I thereby sink below "the stature of God's freemen," nor why to do so would be "an open insult to every cotton manufacturer in the land," nor why the finger of scorn should therefore be pointed at me with the exclamation, "Shame on such reasoning!"

It must now be evident from this that our critic does not at this point discuss the matter in hand. What he argues is, that a high price for one's labor, or a large income, adds to one's dignity, and exalts one's manhood; but I am inclined to think he is wrong even in that. For myself I should not estimate a man by the gold he possesses, by his hourly income, nor by the price he puts on his labor. For divers reasons I prefer to work in the vineyard, the orchard, and the apiary, even at $1.25 per day, than follow the law at $10.00 per day; and Dr. Miller refused the offer of a large salary to engage in an occupation which was not entirely congenial, for the sake of outdoor home life, and work among the bees, where, many years, he accepts less than $1.25 per day with thanks.

"A man's a man for a' that."

I feel quite unwilling to accept the doctrine that Astor is a better man because he receives $16.38 per minute; indeed, I greatly doubt if he is so good; and if one should undertake to argue to the contrary, I should feel "shame on such reasoning," even if a feeling of delicacy forbade its expression. No, I can easily conceive of circumstances wherein I would gladly accept an offer of $45 from Mr. Doolittle for six weeks' work, nor would I feel that I had thereby degraded myself, nor could I make such an offer, made in good faith, a reason for anger.

The rank is but the guinea's stamp —
The man's the gowd for a' that.

After all, the *point* in my address which is so furiously attacked is a very simple one—the cost of a man's labor for six weeks. One who desires to consider squarely the very question will find little place for rhetorical pyrotechnics; and if our critic harbors that desire he may settle it with the greatest ease; but it will not do to mistake for the true question another which is quite foreign to the matter; viz., the value of the time of the owner of the apiary. What a basis upon which to calculate the cost of the production of honey! Prof. Cook's time, we will say, is worth $10 per day; A. I. Root's, $12, and Mr. Doolittle's, $15. Will it do to say, therefore, that Prof. Cook can produce honey at a less cost than Mr. Root, and Mr. Root at a less cost than Mr. Doolittle? Why, if that were so, when we consider that the time of the great mass of bee-keepers is worth only about $1.25 per day, one could not fail to see that Mr. Doolittle must inevitably be distanced in so unequal a race. But it is not so, and we may still expect to see him come out ahead. How does the bonanza farmer, whose time is worth $50 per day, or the great lawyer whose time is worth $100 per day, calculate the cost of the wheat that is produced on his farm? Why, they would figure with the other expenses the amount necessary to hire the labor required to produce the crop; and if either chose to drive team on the farm for a week or a month, he would not be so unjust to his wheat crop as to charge it with $50 or $100 a day for driving team. We ought, in like manner, to be fair with our honey crop. If Mr. Doolittle can get the work of the apiary done at $1.25 per day (we don't work here on Sunday), he ought not to be heard to impose his own labor upon it and charge therefor $15 per day. I have had no trouble in getting it done at a figure considerably less than $1.25.

Turn now to the figures in the criticism in GLEANINGS. It is putting it mildly to say that, when I examined them, I was somewhat surprised. We find yoked together Heddon hives and Doolittle wages! How could they get together in the same apiary? or has he adopted that excellent hive? Is Mr. Doolittle calculating the cost of honey production in his own apiary, or in some apiary where the Heddon hive is known to be used? It is rather startling, too, to find that, because the apiarist has studied the apiarian books and journals, and attended the bee-keepers' conventions, and become thereby skilled, and his time valuable, he allows him $5.00 a day for his work, and then turns around and allows him $5.00 a day for the time spent in reading the books and journals and attending the conventions! and that, not stopping there, he goes on, allowing him the cost of the books and journals and of attending the conventions! I have been much in and out of law offices, and it is evident they are no place to learn how to make charges.

Mr. Doolittle does not attack my figures for cost of plant, except that he takes the hives out of that category; but for what reason, I fail to see. I put colonies of bees, hives and all, at $5.00, which is more than the wholesale market price will warrant. But granting his point for the time, he lives where money commands a high rate, or else he is unfortunate in the cost of his Heddon hives, to make the double interest, 36 cents, on each. Here they cost less than $1.00 each; and as they will last fifty years, with little repair, I could not conscientiously charge double interest, even on that; but, of course, I do not allow common mechanics $5.00 per day, nor machinery in like proportion. However, I see no reason why hives should be separated from the plant and made an extra charge.

It is possible he intends these hives for swarms. If that be so, then of course the apiary should have credit for the swarms, which would make a further very material reduction in the cost of the honey crop.

Freights and commissions will, of course, vary. These charges here for moving the crop in question, 6000 pounds, from my apiary to the railway, one mile, thence to Chicago, nearly 300 miles, with commission for selling, would amount to $65.50; adding cartage in Chicago, say $2.50, makes $68—just my figures which are attacked. It is difficult to imagine where our critic would ship his honey so as to nearly double these figures (his figures are $125), unless he allows all railroad men $5.00 per day too. Seventy dollars for sugar! and, besides, $5.00 per day for feeding it! At the end of the last season (a very poor one) many of my hives had from 50 to 60 pounds of honey, exclusive of bees and frames. It is evidently unsafe to write about what does not come under one's own personal observation, or else perhaps Mr. Doolittle's Heddon hives operate differently. I do not now feed much sugar for winter stores, though last fall I might have made $150 by extracting and feeding sugar, in which case the $70 would go on the other side of the account.

Mr. Doolittle intimates that this attempt to show that the cost of the production of honey may be reduced, or "this lowering the standard of our calling," as he puts it, is made to show to the world a larger net profit. No, he fails to catch the gist of my address. As he says, the average yield has been decreasing for the last twelve years; and, judging from his statement, it is decreasing more rapidly here than in New York, as it is four years at least since we have had an average of 40 pounds. With these facts in mind I undertook to open the question as to the actual necessary cost per pound at different averages to lead to the determination, as near as might be, of the point where all gain ceases, that we might know when we must still further reduce the cost or quit the business. I think my figures are still too high for the great majority of bee-keepers. I am still convinced that it is a laudable thing to strive to reduce the cost of production, and to demonstrate how that may be done, that we may reap all the possible profit, while there is a possible profit, and avoid loss when a profit is out of the question.

I still think, as I thought when I wrote the address, that *economy in honey production is the sheet anchor of the apiarist's hope.* Economy in honey production was the title of that address; it was the thread that ran all through it, and gave it consistency. Criticism misses the mark and loses its value when it fails to discover the heart and life of the thing criticised. Economy in the production of honey is the question of paramount interest to bee-keepers, and it must come more and more to the front. What the vocation now needs most is critically exact statements with full details of the actual necessary expense of money and time required in the production of a crop of honey. The thoughts and pens of intelligent apiarists can not do us better service than in giving us such statements from real life, eschewing fancy supplies and fancy wages. How many will volunteer to keep accurate accounts during the season now opening? R. L. TAYLOR.

Lapeer, Mich.

COST OF PRODUCING HONEY.

VALUABLE POINTS FROM ONE WHO DOES NOT MAKE BEE-KEEPING HIS EXCLUSIVE BUSINESS.

In the Jan. 15th GLEANINGS there is, as I considered it, a very fair and conservative article in regard to the cost per pound of comb honey from a large specialist, Mr. R. L. Taylor. In Feb. 15th number, by Mr. G. M. Doolittle, is another that seems to me wild. These men are both up, away up, in the profession, and their opinions are worth something—in fact, all they can get for them, so I presume it is hardly becoming in a *very* light weight to criticise those opinions or differ with them; but, "fools rush in where angels fear to tread."

Now, from the point of view of one who is a bee-keeper for pleasure (and profit when he can get it), I wish to give my estimate of the cost of comb honey.

As we invoice our stock of hardware (my business) we put down cost to us only of articles and plant in making up our statement of profits or losses for the year's transactions. So, in investments in bees and fixtures it is fair to estimate only interest on the amount actually invested in the business—cost price; in fact, *what it will sell for represents part of the profits of the business* in increase in value, etc.

My apiary to-day consists of 58 colonies, all the growth or product of one swarm which came to me five years ago, without money and without price. It represents in cost to me in cash $184 in hives, foundation, extractor, and other appliances. For variable charges, I know of no better way to get at them than a statement of last season's work of the bees and myself. My account then will stand thus:

BEES, DR.

To interest on investment ($184.00) at 10%	$18 40
To wear, tear, and repair at 10%	18 40
To 5000 sections at $3.50....	17 50
To foundation for same, full sheets	25 00
To crates for shipping....................... ...	13 50
To drayage on honey to depot	50
To freight to destination, 3250 lbs. at 28c per 100	9 10
	$102 40

BEES, CR.

By 3246 lbs. comb honey at $.0252............. ..	$81.80
By 261 lbs. extracted from unfinished sections at $.0252	6 58
By 1650 sections with foundation unused......	14 02
	$102 40

Now, at the low price of $.0252 per pound for my honey, it balances the account with my bees, and still leaves me 47 lbs. of No. 1 wax, and an increase from 35 to 58 colonies to count as a factor in reducing the cost still lower. I paid out not one dollar for labor, and used of my own time only what I could conveniently spare without neglect of other interests—simply used odd moments, and time that would have been less pleasantly and healthfully spent had I not occupied it with the bees; hence I have made no allowance for work in the cost. I also have allowed nothing for commission, for that is not one of the factors in production, and should no more be estimated as a part of the cost than should the profit or commission of the retailer.

Now, I do not wish to present this as a fair estimate of cost from the standpoint of a specialist, and of one who has 150 colonies, and has only his bees as a means of livelihood, and expects to put in his whole time on that number, and do nothing else. But it is a fair one from the standpoint of thousands situated as I am, who take up bee culture, and consider the time spent with the bees as offset by the exercise and satisfaction derived from them only as a pleasure, or as a means of putting in spare time that would otherwise be wasted, expecting the bees to assist in placing the financial affairs of the family on a more substantial basis; and, further, it is one that interferes very seriously with the estimates and wishes of the specialist in honey production, as it will almost invariably break up any idea of his home market proving a profitable one. Mr. Doolittle's estimate, however, appears to be an especially exaggerated one; and he might, to his items of expense, "bee-papers and books, $5; attending conventions, $20; time spent in reading papers and books, and attending conventions at $5 per day," with equal propriety add time spent in nervous and restless tossing in bed when unable to enter the realms of Morpheus, on account of some unsolved problem in apiculture, at the rate of 50 cents per hour; and then the item of *stings*—who would, in cold blood, let a bee sit down on him, and prod in his little javelin for a nickel a prod? That is really too low an estimate; but then, think how it would help run up the cost of honey (you see I have these miserable hybrids).

Without prejudice, it appears to me that, if one counts labor, as must in justice be done, Mr. Taylor's estimate is a very careful and conservative one, as he computes labor at prices that almost any one can hire the work done for if he does not wish to attend it himself, and that is the only fair way.

FOUL BROOD.

Mr. Elmer Todd, on page 133, gives an item in regard to foul brood that is very misleading on the face of it. If Mr. Todd refers simply to the "section of country" surrounding York, he may be entirely correct; but if he refers to Nebraska at large he is very much mistaken; as Saline Co., cornering on York Co., has not a known case of foul brood in it, and a larger portion of Nebraska is in like condition. With a wide acquaintance among bee-keepers I have never before heard of foul brood in the State.

Dorchester, Neb., Feb. 19. C. F. THOMAS.

MANUM AND HIS NEIGHBOR.

HOW MR. MANUM MANAGED FIVE APIARIES ALONE; CONTINUED FROM P. 159, MARCH 1.

"What did you do with the old queens removed?"

"They were used to fill orders for such; and when all orders were filled I used the surplus to start nuclei with, by taking a comb of brood with adhering bees, with the queen; also shaking the bees from another comb with them in order to have plenty of young bees remain with the queen; and to this were added two or three empty combs and one containing a little honey. These nuclei were started in full-sized hives, and from time to time I would give them a comb of hatching brood, and by fall they were as strong as any I had. Some days I would have more orders than I could remove queens. In that case I would take queens from these nuclei to make up the deficiency, and in two or three days I gave these nuclei well-advanced queen-cells, so that by fall I found I had very few of the old queens left."

"Why not give those nuclei virgin queens instead of cells?"

"Because, Charles, they would not accept a virgin queen so readily, having been queenless so short a time; and to keep them queenless the proper length of time for them to accept of one would be a loss of time. Better give such a laying queen. They will be more readily accepted than a virgin."

"Then why not give queen-cells to those colonies where the queens were removed, and save all the bother of running hatcheries?"

"Because, if a cell is given a full colony that has brood in all stages, from the egg to hatching bees, there is more danger of their swarming out when the young queen goes out to mate, than when a virgin is given them. Of course, the virgin is not given until all brood is so far advanced that a queen can not be reared from such brood. But even if a cell, instead of a virgin queen, be given at this time, they will likely swarm; at least that has been my experience, when they would not when a hatched queen is run in, at least not until after the combs have been refilled with brood. Again, by introducing virgin queens we have the advantage of selecting, as it is not always the largest and nicest cells that give us the best queens; hence I always prefer to give a queen whenever I can, rather than a cell, for then I know what I am doing."

"Were you usually successful in introducing virgin queens?"

"Yes, quite successful. At least 95 per cent were accepted at first trial."

"Do you think you got as much honey where queens were removed as you would were they run the old way?"

"I think not, providing there had been a good experienced person at each apiary. However, I think I realized as much profit from my bees as I should to have hired help to run them the old way. There are advantages and disadvantages in both methods."

"How did the crop from your five apiaries compare with that of the other two run the old way?"

"They averaged better than did the other two apiaries; but I believe, could I have managed the two apiaries myself, I could have made a better average with them than the five where the queens were removed (but, Charles, don't tell Fred or Henry of this—please don't)."

"Was there any swarming in the five apiaries after the honey season?"

"Yes, to some extent. I think that probably six per cent of the young queens swarmed while buckwheat was in bloom. These, of course, were the first introduced; and, having filled their hives with brood, and honey coming in at a moderate rate, they swarmed out."

"Of course, you were not there to hive such swarms or care for the parent colony; hence, was it not an injury to them?"

"No; I was not there to hive the bees. They went to the woods; and as to the injury to the old stock, I think that, in most cases, it was no detriment to them, as I visited the apiaries once a week; and wherever I found that a swarm had issued I fixed them up with a laying queen."

"How old a virgin queen is it safe to introduce?"

"I am not positive about that point. I am conducting some experiments regarding this matter. I think, however, that the best results will be attained by introducing virgin queens before they are eight days old. I think when they are two to five days old is the better time; but last season, in some of my yards I was obliged to use some queens older than eight days to save an extra trip; in fact, I have introduced some that were fifteen days old; but I found such old ones were not always reliable when accepted, and I fancied such were more apt to be followed out by a swarm when they left the hive to mate; and in two or three cases such queens proved to be drone-layers; and on the other hand, some of the best queens I have (apparently so last fall) are those that were introduced at from ten to fifteen days old; yet I would not advise any one to use such. When shipping virgin queens I always send those that are but two or three days old."

"While the colonies were queenless, did they not store up large quantities of pollen, to the detriment of the colonies later on?"

"Yes; the bees gathered pollen right along, and it seemed to me at first they would pack the combs full; and, in fact, some of them were pretty well filled; but as the greater part of my colonies were requeened, and the queens laying before basswood blossomed, and as but very little pollen is gathered during its bloom, and as the young queens were laying so profusely, the pollen was consumed to a great extent in brood-rearing before another pollen harvest came on."

"Do you not have some colonies that have an excess of pollen at the close of basswood?"

"Yes, oftentimes. In that case I remove such combs as are well filled, and divide them among my nuclei that I am working up for winter, this being my only method of increase with this management."

"Do you think the bees work as well in sections while they are queenless?"

"No, Charles, not as a rule. Some colonies do; but many do not. The majority of them store the greater part of their honey in the brood-combs, from which young bees hatch out. They are sure to keep such combs full; but with strong colonies, when there is a good flow of honey, work seems to progress as well in the sections as where they have a laying queen, because they so soon get the brood-combs full. The great rush for the sections, however, comes right after the young queen commences to lay. Then all the uncapped honey is carried from the brood-combs to the sections. This is when I get the greater part of my gilt-edge honey, as the sections are filled and capped over very quickly."

"Do you think your bees are in as good condition for winter, by your method of removing the queens?"

"Yes, I do, and, if any thing, in better condition, owing to the fact that, with young prolific queens given them in midsummer, they rear a large amount of brood before winter sets in."

"Do you find it necessary to feed back as much for winter stores by this method as when swarming is allowed?"

"No, I do not; because they, being queenless for several days during the height of clover bloom, are apt to cap over quite a little in the brood-combs, which, of course, remains there for winter's use." A. E. MANUM.

Bristol, Vt.

[You have suggested some very valuable points, inasmuch as they help to clear up some of the difficulties regarding colonies from which queens have been removed to prevent swarming during the honey-flow. We are aware of the fact that many who have tried the unqueening of colonies have found it to be a failure; but as long as such men as Manum, Elwood, and others are successful, it is a great mistake to give the plan only one trial on a few colonies, and then give it up in disgust. The possibilities in this line are too great to be lost. Mr. Manum, we presume, could give us some very valuable points on the minimum cost of a pound of comb honey, and some of the short cuts he has suggested go a long way toward solving the problem. It does not lower our calling, as has been argued, to produce comb honey for less money per pound. If we could secure 20 cts. a pound for comb honey at wholsale, then we might go on and produce honey in the old-fashioned way. It is impracticable to raise the price, but there is a great deal of hope that we can *reduce* the *cost*, and facts and figures in this and the last issue are not wanting to show it.]

MORE ABOUT GRADING HONEY.

DR. MILLER CONTINUES THE SUBJECT.

The requirements of the first grade of honey, as adopted at Chicago, were so exacting that very many thought there could be very little first-grade honey. J. A. Green's highest grade is open to the same objection, and is also open to the objection that it multiplies grades, and too great a number might make trouble about marketing. For years I have sold the bulk of my honey as first class, and have had no fault found with it. I have never selected out any to sell that could pass in friend Green's highest grade, and I don't think a fourth of it could pass muster, if a tenth could. I suspect a good many others would have the same feeling of rebellion that I experienced against a system of grading that would lower the grade of my honey so that I, who had prided myself on raising almost entirely honey of the highest grade, should be obliged hereafter to confess that only a small part of my crop could come up to the mark.

On thinking a good deal about it, however, I must say that my prejudices are beginning to melt away. It's a good deal as one looks at it. If you allow me to say that I raise mostly honey of the first grade, and out of that select a part of the very choicest to sell at a little higher price, then it doesn't look so bad to me. Just this very thing is allowed by the way friend Green puts it. His highest grade is simply a selection out of the highest Albany grade, and is not so very different from the Chicago basis, only the latter has the unfortunate feature of so naming it that the great bulk of honey must be second grade or worse.

The *Review* says, very justly, that the Albany system is too wordy. "Rules for grading ought to be very concise, yet very carefully worded." I suspect it will be a very difficult thing to so word a set of rules that there will be no danger of misunderstanding, and that no two persons can take a different meaning from them. But any approach toward this will be an improvement over the present condition of affairs. Looking at the market quotations as given in the Honey Column of GLEANINGS for Jan. 15, I find the first classification separates honey into "white" and "dark;" the second, "best comb;" then in succession we have "fancy white" and "dark;" "comb honey;" "white" and "dark;" "fancy white" and "other grades;" "comb;" "white" and "dark." It will be seen that the main grading is into "white" and "dark." Now, suppose I look at a quotation and see that I can get 16 cts. for white comb. Just on the face of it I can get 16 cts. for any thing that can properly be called white honey; but if I ship I may find an actual range of 3 or 4 cents according to quality; and as matters now stand it would be a very hard thing to agree in writing just how much my honey would bring, without a great deal of correspondence. I mention these things to show how important it is to have something very definite, and to show, further, that at present we have no system, and very much need one.

The A grade of the Albany system requires that "one face of each section shall be perfect in appearance." I like that idea of "one side;" for when the section comes to its final use—on the table—only one side can be seen; and if the honey on the under side tastes all right it makes very little difference how it looks. There may be some difficulty as to exact agreement in all cases as to what is meant by "*perfect* appearance;" but I hardly see how the wording could be bettered. As to the other side of the section being "perfect in color and sealing, or nearly so," it does seem to me that "nearly so" is unnecessarily vague. It might sound like hair-splitting to name the greatest number of unsealed cells that should be allowed; but I suspect that, if you were to take five men at random, and ask them how many cells might be unsealed to make a face "nearly" sealed, you would get about five different answers. . . . . . I just stopped long enough to try the experiment on three persons (all that I could easily get at), asking each one separately, with the result that one said a section "nearly sealed" might have "seven cells unsealed;" another said "seven or eight," and the third said "eight or ten." I must say that I am surprised that they are so nearly together; but I have some doubt whether there would be so close an agreement if they had never worked together at sorting honey. But even in this case, the range from "seven" to "ten" is enough to make trouble. Would it not be better to be definite and give the exact maximum number of unsealed cells to be allowed? As to color, perhaps there is nothing better than "nearly so."

The second Albany grade is to have "but little unsealed honey." How much more does that allow unsealed than the first, which is "nearly" sealed.

The third Albany grade contains white mixed with inferior, including buckwheat and fall flowers. Does that mean that buckwheat and fall flowers unmixed are included in the third grade, or that buckwheat and fall flowers are included in the inferior honeys that may be mixed with white? It would hardly seem to mean that these two kinds unmixed belong in this grade, for, immediately afterward, buckwheat is put in a separate class by itself. On the other hand, if these two kinds be allowed in the third grade only when mixed with white, then fall flowers, pure and simple, have no place in any grade. There's trouble somewhere.

Possibly there may be some of the readers of GLEANINGS as ignorant as myself; so, Mr. Editor, will you please tell me what is meant by "boxes known as 'pieces' "? and why put a "private" mark on them?

Let me now give just a little further glance at friend Green's system. I like the man so well that I should expect something good from him; but no faults should be passed by unchallenged. I have already noticed the fact that the first three grades all make the same demand as to quality, and that throws every thing not of good flavor into the "M" grade. Possibly this is all right; but there is such a disagreement in tastes as to what is "good flavor" that it may not be wise to bring them in unnecessarily. Moreover, as the public taste now stands you may formulate all the rules you please, and the whitest honey will bring the highest price without being tasted. Still further, is not every white honey good enough in flavor to suit the general consumer?

The general spirit of his "A" grade is much the same as the Albany, and is quite satisfactory. But would you allow a single cell of pollen to throw a section into the "C" grade, if it were perfect in every other respect? By the way, Albany says not a word about pollen.

In the "C" grade, "sections must be nearly filled, with few or no unsealed cells." In that, the words "nearly" and "few" are indefinite. Couldn't a little arithmetic come in there? Again, at the close of the "M" grade "well sealed" is indefinite.

In the extra select, if I understand it rightly, a single unsealed cell, in the line of cells touching the wood, rules a section out. Isn't that a little too exacting? If a section were perfect in all other respects, and a little propolis carefully scraped off the wood left a slight discoloration, would you throw it out of the "extra select"?

I hope it will not be understood that I have any intention of treating with disrespect the efforts already made toward establishing a standard. Far from it. I am very grateful for what has been done, and am free to admit that *I* am not able to get up a scheme of grading satisfactory to myself. You may then ask, if I can not tell what ought to be done, what use there is in my talking about it. Let me illustrate. Emma has been doing some very nice work to-day painting in oils. She has been very glad to have me point out defects for her to remedy, although, if I were to take the brush into my own hand, and attempt to make a picture of a bee on a flower, a label might be needed on each to distinguish the bee from the flower. After further discussion, finding out more fully the views of others, it is possible I may know enough to formulate what I think would suit me, in which case I shall not hesitate to try my hand at it. C. C. MILLER.

Marengo, Ill.

[Boxes known as pieces?—Mr. Elwood explained this on page 155, March 1st issue.]

THE GRADING OF COMB HONEY.

J. A. GREEN CRITICISED STILL FURTHER.

Friend Green says in GLEANINGS, page 44, "I must say that I am not at all satisfied with either of the systems of grading comb honey that have been proposed. That adopted at the Northwestern convention was rather too exacting in some of its requirements, and, in some respects, was incomplete." He then gives instructions for grading comb honey as adopted by himself, which, it seems to me, are open to the same criticisms he bestows upon the system adopted in Chicago. He says that honey in the best and second-best grades should be "light-colored" and of "good flavor." Now, this matter of "color" and "flavor" was duly considered in Chicago; and it was thought best, when all things were taken into consideration, to omit them both. To include "flavor" would make heaps of trouble to both dealers and bee-keepers. For instance, "light-colored" honey may be white clover, sweet clover, basswood, willow, the sages of California, etc. Now, the flavors of these different kinds of honey are so unlike each other, and so peculiar, that what would suit one consumer would not suit another. There are plenty of people who dislike exceedingly the flavor of basswood (linden) honey. Now, suppose the retailer buys a quantity of basswood honey, warranted by the instructions as laid down by friend Green to be of "good flavor," and he sells the same to consumers who happen to live where basswood honey is unknown, and they so dislike its flavor as to find fault with it. The retailer would then be quite apt to complain to the wholesaler, and he in turn to the producer, and the objectionable feature would have to be adjusted in some way, and chiefly at the expense or loss of the bee-keeper. The same may be said in regard to some of the other kinds of light-colored honey. The only safe way for both producers and consumers to pursue, it seems to me, is to let flavor alone and give no heed to it in grading comb honey. Let the eye alone determine the grade to which any honey in the comb belongs. The sight is by no means so apt to get people into trouble in regard to honey as the taste.

The idea that only honey of "light color" can be of the best grade is preposterous, for there are many consumers who prefer dark honey, or of amber color. Much depends upon one's taste, and what market it is. Then why make any ado about color in grading honey, provided it be, in each crate, of one color, or "uniform in color," as per the Chicago instructions? This enables the dealer to get any color of honey he prefers for his market, whether it be dark, medium, or of light color; also of any grade. I see no good reason why any one should worry about the color so long as consumers can have their choice.

The Chicago convention gave no instructions how to mark the several grades of honey, but should have done so, perhaps. I see no objection to the use of letters in case they are taken in rotation. I don't like the idea of skipping around in the alphabet; for instance, from A, B, C, to M. Why not use D for M? Can any one give a valid reason? In case we use letters, why not use them in such a way that consumers can understand their meaning as well as producers and dealers? The letter A is good enough for first grade, or for the best grade, unless it might be better, all things considered, to use the double A A; then the single A might be used for second grade; B for third grade, and C for fourth grade, which, in my opinion, are grades enough. M. M. BALDRIDGE.

St. Charles, Ill., Feb., 1892.

GRADING HONEY.

AND THEN MR. GREEN CRITICISES HIS CRITICS.

I hope the discussion of this subject may be continued until we arrive at some sort of understanding as to what is desirable. If we can agree on only a few essentials, I have faith that we may yet be able to unite on some system, even though it may not be entirely satisfactory to all or to any.

In the first place, how many grades shall we have? I will readily admit that those systems which keep color and general appearance or condition distinct, such as those of Mr. Baldridge, Mr. Frazier, or Mr. Mandelbaum, as given in the *Review*, are more philosophical, more systematically exact, than one in which they are considered together. The trouble is, they are too elaborate and complex for actual use, at least until the business of selling honey has attained a higher development than it has at present. Any system which divides honey of good quality into more than four grades is unwieldy, and will break down in practice.

Some object to the establishment of a superfine grade of honey—a grade that shall be better than the great bulk of nice honey. It is probable that there are some localities where it would be impossible to produce the honey demanded for the "Extra select" grade. There are many more bee-keepers who never can produce such honey until they improve their methods. But the fact remains, that there are some bee-keepers who can produce this extra nice honey, and some of them get an extra price for it too. It is right that they should. It is possible, considering the small quantity of such honey, that it would not be advisable to place it on the general market to be sold on commission; but such honey will be produced, and the producer will receive his reward.

As Mr. Elwood says, it is impossible to express on paper all the variations which must be taken into account in grading honey. In writing out my system it was my intention rather to describe a typical section of each grade than to lay down unyielding rules. A section that is particularly nice in some respects may be permitted to be slightly defective in others. Thus I often place in the highest grade a section having some cells unsealed. But they must be of the line of cells touching the wood, and must contain no honey.

The "A" grade contains, as a rule, only white honey; but a slight discoloration of the bottom of one side of a comb is not sufficient to throw it out, provided it is up to the standard in other respects.

For a section to have the comb unattached at the bottom is a serious defect. This may not detract much from the appearance, but it renders it much more liable to be broken. This increased liability to breakage is not only during shipment, but perhaps more during the handling it receives after it reaches the hands of the retailer and consumer. At this time it is very undesirable that it should be packed upside down as often advised. The section is lifted by the bottom, which, unless there are attachments of comb to strengthen it, is apt to come loose, letting the section drop. I have seen many a section smashed in just this way.

I have produced many hundreds of pounds of honey, on the sections of which the closest examination could scarcely detect the slightest stain of propolis. Mr. Elwood is taking too restricted a view when he says that the honey-boxes are not usually seen by the purchaser or consumer. Although in many places the grocer takes the majority of his orders by telephone or at the home of the consumer, most groceries are still ordered by the consumer within the grocery. If it were not so, it would be much worse for the honey-market, for it is a well-known fact that many people never buy honey unless they see it or have it brought to their notice. The successful seller of honey keeps it prominently in sight, often taking it from the case and stacking it up on counters and in show windows, and a soiled section detracts much from its attractiveness.

Personally I entirely agree with Mr. Elwood in regard to sections not full of honey. Such sections I generally give away or use for feeding. I mentioned them in my fourth grade, simply because I knew that such honey is sold by many bee-keepers, and I wished to have the system complete.

Dr. Miller takes me up on the difference between the meanings of "flavor" and "quality." What I meant was, that the two higher grades should be of good flavor *and* quality, and the next grade the same, though I would admit to it honey not quite so good as would be needed for the better grades. You see, doctor, it's only because I'm not handy in the use of the English language, as you have somewhere expressed it, that it happened so. Perhaps it would be best to use the words "of good quality" for all of the first three grades. I think it well to have this condition, because I once had some honey sent me from Missouri that was beautiful to look at, but with a flavor that made it almost uneatable to me.

Straight combs should be graded higher than crooked or uneven ones, because they look better, and consequently sell better, are not so easily injured, and are more convenient to sell.

Dayton, Ill., Mar. 8. J. A. GREEN.

SPRAYING FRUIT-TREES.

P. H. ELWOOD RECONSIDERS THE EFFECT OF ARSENITES ON BEES AND LARVÆ.

The discussion in Albany on spraying fruit-trees while in bloom has called forth criticism. Some think that State Entomologist Lintner (as if we could tell how far a bug-man would jump) ought not to have been permitted to make such statements before the convention. But which, may I be permitted to ask, would have been the better place for Dr. Lintner to express his opinions—before a meeting of fruit-growers, such as he usually addresses, who would fall in with his ideas, or before a convention of bee-keepers who would and did controvert them? Evidently the doctor had nearly made up his mind to advise spraying during bloom, and undoubtedly would have done so had there been no evidence against it. When he left the convention he was fully satisfied that it would be best to recommend, as heretofore, no spraying until after blossoming. Nevertheless, the doctor wished more conclusive testimony. He thought Mr. Smith's bees may have died from other causes, or from poison administered in some other way. He asked that a committee be appointed to bring the matter before some of our experiment stations, particularly the Rhode Island station, which has a department devoted to apiculture, so that we might have full and complete tests. He thought the result of such experiments would be accepted as authoritative. Prof. Lintner is not to be blamed for the position he takes; for if you will turn to April 15th GLEANINGS, 1891, you will learn that the late Mr. Ashby, a very reliable, intelligent man, believed, after testing the matter somewhat, that Paris-green solutions or mixtures of the standard strength do not injure the mature bee. And I notice by the last *American Bee Journal* that Mr. Smith himself calls for experiments that will be satisfactory; and well he may, for he discloses the fact that his bees were probably poisoned by a solution of Paris green of four times the recommended strength, or four times as strong as can be applied to the apple without injury to the foliage. There are a number of points on which we need light. For instance, we want some scientific men to visit orchards at the time of spraying, and test the strength of the solutions as actually applied to the trees. There are good reasons for believing that the poison applied from near the bottom of the barrel is often much stronger than that applied earlier. Paris green is much heavier than the liquid into which it is usually put; and unless the agitating apparatus works perfectly, the above result will appear, so that this factor would have to be taken into consideration. Or the solution may be applied of the standard strength, and a drying day may so evaporate the water as to leave it very strong. This sometimes injures the foliage. It would be well to know how it affects the bees. In combination with lime the arsenites (London purple and Paris green) may be applied of greater strength without injury to foliage (see Bulletin No. 35 of Cornell Experiment Station). Gillette, of the Iowa Experiment Station, says, "London purple can be used at least eight or ten times as strong without injury to foliage, if applied in common Bordeaux mixture instead of water." As yet, however, the Bordeaux mixture can not be thrown into the tops of tall trees. Again, the arsenites are of various degrees of solubility in water. Pure Paris green is called insoluble, but it is not. London purple is more soluble. Over 50 per cent of the arsenic in the London purple used at the Cornell station was soluble in water. It would be well to know which usually kills the bees—the part soluble in water or the solid particles. The difference in solubility of the poison may perhaps explain why Prof. Cook's bees were poisoned when Mr. Ashby's were not, with mixtures reported the same. Mr. Ashby thought the honey-bee in gathering nectar is able to reject the minute particles of foreign matter. Our best authorities, however, do not agree with him. If Mr. Ashby was not right, then the size of the particles of undissolved poison, no matter how weak the mixture, becomes important, as it will take a very small grain of arsenic to poison a bee. Taking weight only into consideration, it will require only a millionth part as much to poison a worker-bee as an average-sized man. In the case of Mr. Smith's bees, the brood is reported to have been poisoned quite as extensively as the mature bees. Dr. Lintner asked the convention if this great loss of brood could be accounted for by their being fed undigested pollen from the sprayed trees, as explained by Prof. Cook. The writer answered him that the pollen fed the worker larvæ was always partially digested in the stomach of the nurse-bees. Secretary Dadant promptly corrected (?) him by saying that after the fourth day, the larvæ are fed unchanged or undigested pollen, and therefore that the loss might be so accounted for. Prof. Cook and Dadant are mistaken in their statements and teachings, for it is a well-established fact that the worker larvæ do not receive undigested pollen at any period. I refer to this subject again because of its importance. If the larvæ were fed pollen just gathered from the poisoned trees, the explanation would be easy. During the first three days the larvæ receive nothing but digested food; and after that the same with honey added. If worker brood is poisoned at all by pollen it is by pollen that has been as far as the second stomach of the nurse-bees. If poisoned by honey fed to larvæ over three days old, our authorities would have us understand that such honey has been no further than the first stomach. In the human stomach, arsenic does not poison for some time, and we should expect not only equal but much greater immunity from poison in the honey-sac of the bee, since it is undoubtedly true, as Cheshire says, that true digestion does not commence here. Thus it is possible for bees to carry a deadly poison into the hive, and either feed it to their young or deposit it in the cells.

A few years ago one or more of our leading entomologists falsely accused the bees of puncturing grapes, and recommended the free use of poison. As no limit was given as to the strength of the poison to be administered, such advice was fraught with danger to the human family. Truly the time has come for putting more restrictions on the public use of poisons. The writer asked Dr. Lintner why he thought, if arsenical poisons of a certain strength so readily kill noxious insects, that they will not injure bees. He replied that, in the case of the the codling moth, as well as with some other insects, the effort was to kill the newly hatched larvæ and not the mature insects, and for this purpose a very weak poison would be as effective as a very much stronger one for full-grown insects. Now, within the bee-hive we have just as young larvæ that may be poisoned; and in the absence of further knowledge we may assume that a poison strong enough to kill the newly hatched apple-worm will likewise kill the newly hatched bee-worm, or larva. Thus, if the doctor's own statements are admitted, we have sufficient proof to condemn the practice of spraying during bloom, for the very weak arsenite that passes safely through the first stomach of the field-worker, or safely through the second stomach of the nurse-bee, will surely kill the tender larva when it reaches it. We have accepted the statements of our western friends, that the brood in Mr. Smith's hives was poisoned, as undoubtedly it was, but we have no conclusive proof of it. The brood, in the absence of the mature bees to feed and protect it, would have perished, and been dragged out in the same way. We need to know what part pollen has in this poisoning, whether it has any or every part. We also need to know how strong an arsenite the blossoms of fruit-trees will bear; for it may be that the blossoms are so much more tender than the foliage that it will be impossible to spray them with any thing strong enough to kill even the most tender insect.

There is plenty of material here for experiment; and the point is not, have we any thing to prove, but have we any one to prove it? The United States have a young man in their employ, located at the Michigan Agricultural College, and caring for its apiary of seventy or eighty colonies. It is not to be expected that, after looking after this number of stocks, he will have much time for experiment. The government has also an able man (Frank Benton) at Washington; but all the bees they furnish him for experimental purposes are some specimens preserved in alcohol. Dr. Lintner referred us to Rhode Island, the smallest State in the Union, as the one most likely to aid us. This brings us to the question, "What ought the States and general government to do for apiculture?" P. H. Elwood.

Starkville, N. Y.

[Our correspondent has indeed suggested some points on which we need more light, We most heartily commend Mr. J. H. Larrabee, of the Michigan Agricultural College. He has all the facilities at hand, and we believe he could furnish us some valuable data. This is a case where science and practice go hand in hand; and at what better place can these things be determined than at an experiment station, under the auspices of the State or national government?]

HOW THE BREEDING OF OUR BEES IS EFFECTED BY THE MATING HABITS OF QUEENS.

A NON-SWARMING STRAIN OF BEES; SHALL WE GET IT?

Every apiarist recognizes the necessity for good queens. Those reared under conditions where sufficient heat and food are absent are not wanted. Good, healthy, perfectly developed queens are longer-lived as well as more prolific. Thus when we breed and mate a queen-bee, we determine the character of a colony for a number of years. Besides desiring to breed the queens large and healthy, we wish to preserve certain qualities present in the ancestors. In the direction of color we have succeeded somewhat; but have we made any progress toward preserving the valuable traits of perfect wintering, honey-gathering, and non-swarming?

The Albany convention, without doubt, recognized the fact that we have made little or no progress in the breeding of non-swarming bees, as, in the scale of points that is adopted for judging the Italian bee, there is no mention made of the trait of non-swarming.

W. F. Clarke, in his essay read at the same convention, was of the opinion that swarming is not a normal condition. Pres. Elwood believed that there was a difference in strains (not races) of bees upon this point. The opinions held by both these gentlemen show that there is a belief lurking among apiarists that there is something in it. Though non-swarming strains of bees are often boomed for a while, we do not remember that they were ever a success. We of America are too anxious for the dollar of to-day to work patiently for a series of years to attain any degree of success with non-swarming bees. It is desirable that the queens of a whole apiary, and perhaps for miles around, be bred with this in view, and drones as well as queens selected.

Let us now consider why we have not succeeded better in our breeding efforts toward this end. The methods of queen-rearing in vogue in most apiaries are against any results ever being attained. Nearly all queens are reared from swarming cells, and the colonies that do not swarm do not survive. I believe that nine-tenths of all the queens in the land are bred under the swarming fever, and this has been kept up for generations uncounted. These tendencies, having thus existed, have become one with the instinct of the bee. Can we even doubt that they were implanted there at the creation to be for ever the means of preserving and extending the species? The swarming fever is not present, we know, except as developed by external causes. But have not the natural laws of selection weeded out those colonies swarming under adverse circumstances, till, as before, swarming under certain outside conditions has become coexistent with the natural instinct? The possibility of partially overcoming this tendency is not disputed. All who have tested the Carniolan bees acknowledge that they are great swarmers. Black bees do not, I am sure, swarm as much as Italians. Oh, yes! "there is a difference in strains of bees." Now, does not the existence of this difference prove that it is possible to breed out *somewhat* this habit of swarming? We have non-sitting strains of poultry; some breeds of sheep nearly always produce twins; and so it is, that, wherever an attempt has been made to breed with this end in view, progress has been made.

The greatest obstacle in the path of the apiarist desiring to breed carefully is the mating habits of the queen-bee. Whirling away on the wings of the wind, she seeks a suitor perhaps far from home, and the breeder hopes she has mated with a drone of a certain colony—perhaps knows she has mated with a yellow drone in localities where none but yellow bees are kept. The rest is generally all guesswork. The drone-trap can be made to control the flight of drones in an apiary; but great care and labor are necessary; and even then one does not know that a certain queen is mated with drones of a certain colony. From facts and incidents recounted often in our bee-papers, we find that the queen seems to *prefer* to mate with a drone from a distance. I have often found it so in my own experience.

Carrying out the Dzierzon theory of parthenogenesis we see that the drone is the son of its mother only, and may have quite different characteristics from the worker-bee of the same colony. To become acquainted with the drone and his character we must go back to the grandmother and her colony. This fact is worth remembering; yet how few, even of the most careful breeders, give it any attention!

Some years ago, as most of us remember, N. W. McLain conducted some experiments in the fertilization of queens in confinement. He reported success, both in a screen house and in a block held in the hand in certain cases. One successful operation is enough to give great hope, and furnish ground for future work; but the failure of careful queen-breeders in even obtaining one success by these methods, and the incredulity, I might almost have said ridicule, with which many regard the whole matter, has deterred me from undertaking any thing along this line. I have searched most thoroughly for other methods by which to accomplish the mating of queens with desired drones. No plan seems to me to promise more than that of compelling the queen and drones to fly earlier or later in the day than they would if allowed to fly when nature or instinct told them the mating would be surest.

If any way can be suggested, aside from the one just mentioned, as probable or even possible, to attain success, I should hope to devote myself most earnestly to making its success an assured fact.

As there is, without doubt, much more to be learned about the mating of the queen, we may, by a more careful study, discover something that will shed light upon the subject, and open a way to success. I should be glad to receive and arrange reports of such observations, and present the results to bee-keepers, and will try to learn something new in this direction myself.

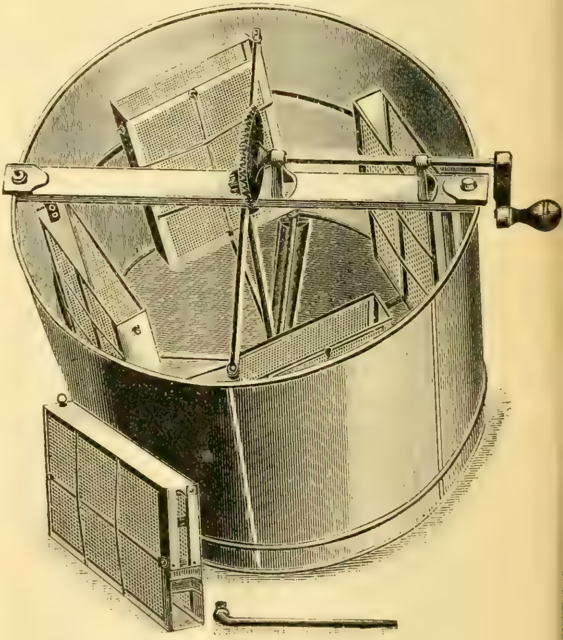
Should control of reproduction ever be secured, all these points in breeding, toward which we are striving, would become easy, and real improvement in the races of bees would be made; honey would be cheaper, and adulteration less. But who can tell the train of results that would follow? J. H. LARRABEE.

Agricultural College, Mich.

THE GOOLD REVERSIBLE HONEY-EXTRACTOR.

A NEW REVERSIBLE AUTOMATIC HONEY-EXTRACTOR.

Herewith is an illustration of a reversible honey-extractor made and patented by E. L. Goold & Co., Brantford, Ontario. It can be made either as a two-frame or four-frame machine. For a two-frame Langstroth a can 23¼ inches in diameter is required; for a four-frame the diameter must be 27 inches. The baskets holding the combs have attached to them an eye through which a rod passes. Joining the upper and lower arm upon this rod the basket swings from side to side. There is, therefore, no loose hinge which can be thrown out of place. The method of reversing is by means of a rod running from the center of the can and center-shaft to basket, turning up and running in a groove shown in the basket lying outside of the can in the illustration. The end turned up has a small roller on it, which lessens friction. This is the part that does the reversing. The baskets are reversed as the motion is reversed, and the process with the two or four frames, as the case may be, must be simultaneous. This machine took the first prize at the Toronto industrial exhibition last fall for the best and most practical invention not hereto-

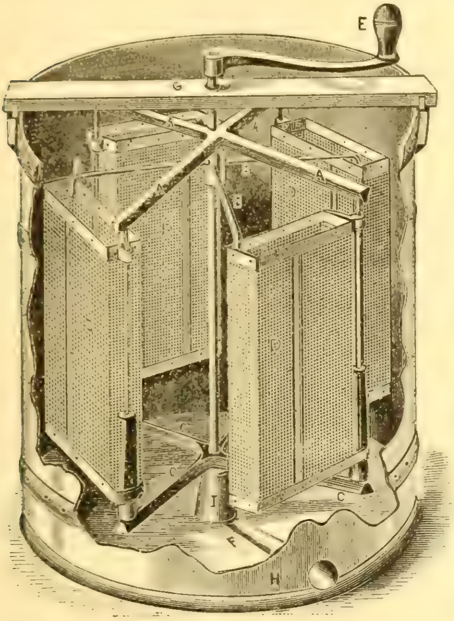


GOOLD'S NEW REVERSIBLE EXTRACTOR.

fore shown at that exhibition. There were five inventions competing. R. F. HOLTERMANN.

Brantford, Ontario, Can.

[The cut and description above does not make the principle of the extractor entirely plain. Reversing is caused by a positive lever motion. These levers radiating from the center shaft work in a slot in the bottom of the comb-pockets. Reversing the crank reverses the center shaft, which in turn revolves the levers a little way, and this causes the pockets to be swung around. Perhaps the idea will be understood a little better by the engraving which we made some months ago, of their first machine, only that the levers, in that case, were placed *above* the baskets, whereas they are now put under so as to be out of the way of the combs. The peculiar feature claimed for this extractor is, that the comb-pockets when at rest are out of the way of any supporting arms for putting in and removing combs; and although our friend Mr. Holtermann does not say so, we presume the manufacturer also dispenses with the chains.



We tested one of their extractors; but, for some reason, we were not able to make it work satisfactorily—at least, not as well as the Stanley in actual service in extracting. We have since been informed that the manufacturers, E. L. Goold & Co., Brantford, Ont., have overcome some of the defects encountered in their first machines.]

FOUL BROOD AND THE SALT CURE.

W. L. COGGSHALL EXPLAINS HIMSELF.

On page 84 Mr. M. M. Baldridge asks for my method of administering salt for foul brood. Mr. Baldridge need not have said that he was no novice, as I have always recognized him as an able and practical bee-keeper, for there is but little printed in the journals that has not been read by me in the last 25 years, although I am not quite 40 years old yet. I notice the editor threw cold water on the theory that salt or brine would cure foul brood; but I thought that the editor and Prof. Cook had tried it scientifically, so I said no more about it. I had tried it only in an experimental way four or five times with as many colonies, and it was effectual every time. I used it only twice, at intervals of ten days or two weeks, and each colony came out all right—no more brood died. Let me say right here that it might not have been foul brood. Well, if it was not, then I am out of the race.

What is the cause of foul brood or diseased brood? A great many say chilled brood is the first cause. Well, a man can not be a bee-keeper without being a little theoretical. My theory is, starvation, the bees not being able to get out in the spring and get what honey the young bees require to live on. This will cause diseased brood every time, and I have cured it *every* time, and it has never done me any harm.

Now for the cure (with me at least). Take a pail of soft lukewarm water, and dissolve what salt you can in it by stirring it ten minutes. It will not do any harm if it is strong enough to keep pork in. Take the combs out of the hives that are affected (I use the brushbroom that I use to brush the bees off when I extract, made of fine broom corn). I sprinkle the combs, bees, brood, and all, lightly. It will not hurt the brood at all. Once a week is often enough in extreme cases. In the meantime leave a chunk of salt as large as a hen's egg in front of each hive in the apiary. Be sure to put it right up close to the entrance, where it will dissolve, and the bees will get it. I usually keep a nail-keg or a barrel filled with sawdust, under the eaves of the bee-house. Put on a wide board, with salt in the top. It acts as a leach, and the dust holds the moisture. If it does not rain often, throw in a pailful of water, and you will have less trouble with the bees bothering your neighbors.

Now, brother bee-keepers, do not forget the above, and you will have less trouble. The easiest way to get along with trouble is not to get in.

I will tell you how I get rid of or cure another trouble that some of the bee-keepers have had ni removing the queen. They attribute the trouble to the queen, when it is not she at all. I refer to the brood not being capped up, and they sometimes hatch out without being capped. The cause is, that there are not enough young bees to cap over the brood. Remove two frames of brood, and replace them with two frames of hatching brood from another colony. I will admit, that removing the queen will accomplish it; therefore by the time you get another queen in there will be enough young bees hatched to cap over the remainder. If you should put the old queen into a strong colony you would generally find her a hustler; hence you condemn the old queen when it is not she at all—or, at least, that is my experience.

W. L. COGGSHALL.

West Groton, N. Y., Feb. 15.

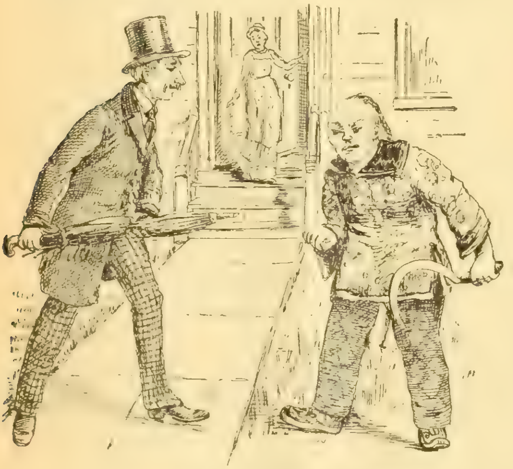
[We can not believe, friend C., that you had real foul brood. If it will not yield to strong antiseptics, as we have tried repeatedly, it is unlikely that it would to a mild antiseptic like salt. We have seen many forms of chilled brood that resembled, in every particular, foul brood, and yet this would always go off at the approach of warm weather. Now, if we had salted these combs we might have supposed that we had foul brood, and that salt cured it. In dealing with foul brood it is dangerous to experiment with unknown or partially tested remedies. As we have before explained, chilled brood or dead brood may be a favorable medium for the lodgment of the germs already floating in the air; but they can in no case give rise to their growth. All scientific authorities, as well as practical experience in the apiary, vouch for this.

We give our friend W. L. Coggshall the credit of being one of the brightest and most successful bee-keepers of York State, yet we fear he has been misled in his observations respecting foul brood. It has been quite conclusively proven that the disease can not start without germs. He is quite correct in regard to bare-headed brood.]

RAMBLE NO. 55.

IN NAPA VALLEY; A TENDERFOOT'S BLUNDERS AND MISTAKES IN CALIFORNIA.

John Chinaman is something of a factor on this coast. There are several thousand in Sacramento, and a visit to Chinatown is always a place of interest. We seem to be suddenly transported to a different clime, where we find people with an entirely different dress, language, and ways of doing business. The Chinese have almost complete control of the laundry business. Many are also employed as servants in private families, and many work on ranches, or rent ground for gardening purposes, at which they are adepts, not only at producing, but also in marketing, and their wagons are seen on the streets at all hours of the day. If they can not afford a wagon, a hand-cart is employed. They are very faithful, and not quarrelsome. But in our first experience with a Chinaman we found an exception. Our cousin's wife employed a Chinaman to cut the grass on the little lawn in front of the house for four bits (50 cts.). When he had cut about two-thirds of it he struck for higher wages, and wanted four bits more before he would finish the job. His actions while he flourished his sickle frightened the ladies, and the Rambler was called around to regulate the Chinaman. But, no; he still flourished his sickle, and shouted. "Melican man makee Chinaman workee too muchee. Me lelbow muchee tired. Me blely empty; me muchee hungly; me workee no more for four bits; me fightee Melican woman, Melican man." Our regulation was a failure except to prevent an attack upon the Melican woman. He was paid the four bits, and he went off muttering about Melican woman. Melican tenderfootee no sabe (understand) poor Chinaman. The Rambler procured a sickle and soon finished the job.



ME MUCHEE TIRED.

Chinamen, though adepts to learn American trades, have, fortunately, not taken to bee-keeping. About the extent of their work in this line is to put up boxes and catch absconding swarms, and sell them to some apiarist for from four to six bits. If they were expert bee-keepers we are not sure but they would monopolize the business in this State.

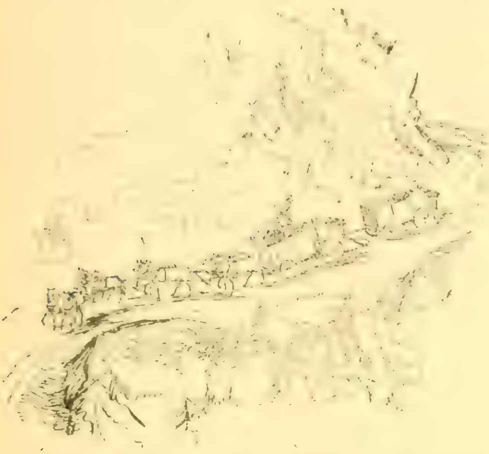
Being recognized as a tenderfoot by a Chinaman, a kind old lady, many years a resident of California, sought to pour oil on our wounded feelings by giving me lessons in California customs.

"Why! laws-a-me!" said she, "me and my old man made no end of blunders when we first came here. The first grocer's bill we received had 'spuds' charged to us in several places. Says I, 'William, I never ordered a spud—not one. Why, a spud is a sort of a round blunt stick to transplant beets with. The idee of putting spuds on a grocer's bill! it's outrageous. That grocer is a barefaced cheat;' and I got so excited that I posted right off to the grocer's, fully determined to give him a piece of my mind. I sailed through the door kinder lofty, and, says I, 'You sell spuds, do you?' 'Yes, m'am,' he says, kinder pert; 'will you have another sack—some fresh ones just in?' 'Spuds!' says I: 'spuds! Why,' says I, 'them's taters.' 'Why, yes,' said he, 'that's what tenderfeet call them, but they are spuds here.' I jest went right home a humbler and wiser person, and me'n William wouldn't have said a blamed word after that, if we'd been charged with bean-poles and a whole picket fence on our bills.

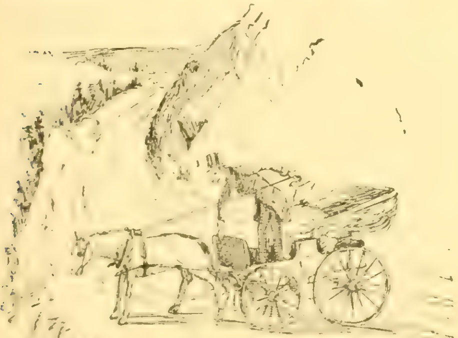
"And then I made another wretched mistake. I called upon a neighboring lady. I thought she appeared very sad. Finally she said her husband was in the corral; and, says I, just as sympathizing as I could, 'Poor man! what did he steal?' '*Steal!*' said she, with flashing eyes. 'Why, yes,' said I; 'ain't a corral a jail?' Her anger changed to laughter. Said she, 'Anybody'd know you're a tenderfoot. A corral is where we herd our horses and cattle.' 'Well,' says I, 'why can't they call it a cowyard then, and not rack the dictionary for hard names?' I felt much humbled, and William made no end of fun of me; and when he discovered that I lay awake half of the night resolving things, he said I would get to be as bad as the woman (I guess it was a man) who was so humble she had to wake up in the night to rest her face."

After this series of lessons I went forth again with renewed confidence and rambled to Napa Valley, which is well over in the Coast Range of mountains, about 70 miles west of Sacramento.

Again orchards of various kinds of fruits, and extensive vineyards, were encountered in the valley, while the hilltops were brown and dry. Raisin vineyards were quite numerous, and trays about two feet square were distributed between the rows, upon which the grapes were drying; after the sun had performed its work, the grapes were put into boxes and piled one on the other for the sweating process, after which they were sorted and layered into boxes ready for market. The products of many vineyards are used for wine-making, and the grapes were being "packed in" from the mountains. The term pack is used here altogether for the word "carry." "Pack in that board," "pack a swarm of bees from the canyon," etc., are often heard. As nearly all articles in early days were packed on mules, and are now in remote places, this term is therefore still used. Loads of fruit and other materials were met that would make a whole eastern family run outdoors and fall over the front gate to see. Eight horses attached to a huge wagon: in the rear, another wagon attached called a trail wagon: wabbling along, drawn by two chains, and directly behind the rear wheel, is the blocker, 18 inches long, and nearly a foot square. The break-lever runs up over six feet, to which a rope and small tackle-block is attached, and with which the driver can exert a powerful pressure on the wheels: and on some mountain roads it is also necessary to chain the trail-wagon wheels. The idea of using a trail wagon and all the teams ahead is to save the labor and expense of another driver. Expert drivers are paid over $100 per month. Some of these wagon trains were loaded with loose grapes, and these were thrown out with a pitchfork, upon arrival at the winery. Loads of honey and loads of bees are packed down the same way, and merchandise drawn back.



LOADS OF CALIFORNIA HONEY GOING TO MARKET.



WE CAME TO A STANDSTILL.

In Napa City I procured a livery rig, and went out toward the mountains, according to directions, to find Mrs. J. D. Enas. This was my first experience in hunting up a residence in the country in California, and it was somewhat educative. One of the liveryman's directions was, to inquire of any one, for everybody knew Mrs. E. My first inquiry was where two ways met, and I congratulated myself that one of the aforesaid teamsters was so near. But in answer to my question, the following lucid information was given. "No sabe English. You sabe Spanish?" Three teamsters in succession gave about the same answers. Two residences were called upon, but the families had just moved in, and I moved out and on up the mountain until the way became so wild, picturesque, and precipitous that my horse concluded he would stop. We counseled a while on the situation, and, concluding that no widow woman with promising sons and daughters would live in that place, we turned around; and, after some more tribulation with an Italian, also a "No sabe" man, I found the residence of Mrs. Enas, up through what some term the chapperal on the side of the mountain.

Mr. Enas came from New York to this mountain home, several years ago, seeking a healthful abode. Mr. Enas' name was familiar to the readers of the *American Bee Journal*, and I think GLEANINGS, several years ago, as a contributor to its columns. He had here at one time over 100 swarms of bees, produced honey, reared queens, and purchased an engine and machinery for the manufacture of hives and sections. But before he could do much at the latter business he was called to a higher realm. After his death, his wife and daughters, with commendable enterprise, manufactured foundation, and dealt in supplies, and are well known to the bee-keepers of California. They have but few swarms of bees now; but I was assured that this region was excellent for the production of honey. This is not a sage locality, and there are not many apiaries in this valley. The Rambler visited Mrs. E. with a view to purchasing the aforesaid machinery; but a change of plans sent me to a different portion of the State. I had no use for machinery, and I believe it is yet for sale.

After a very pleasant hour, with something less than a dozen charming ladies, good time was made down the mountain. I silently passed the swarthy Spaniard, and soon upon the streets of Napa City strode the RAMBLER.

THAT BOUNTY.

A CLEAR, CONCISE STATEMENT OF THE CASE, FROM THE PRESIDENT OF THE N. A. B. K. A.

In the discussion of the question whether the government ought to give a bounty to producers of honey as well as to producers of home-made sugar, in order that we may compete with Cuban or South American honey-producers, the fact seems to have been almost lost sight of that foreign honey is not admitted free, as in the case of sugar. There has been a specific duty of 20 cts. per gallon on honey imported, since 1864. This is equal to about one and two-thirds cents per pound. If honey had been put on the free list, then might we be pardoned for demanding a bounty. If we are not sufficiently protected now against Cuban honey, it seems to me the proper thing to do is to ask that the tariff be increased. It has been said, that comb honey did not need any bounty. If that is true, and if it is also true that our only important competitors in the production of extracted honey are the West Indies and South America, which honey I suppose does not enter into competition with our best Northern or California extracted for table use, it seems to me that we should endeavor to put on the market such an article as will recommend itself to the consumer as superior to table syrups. If it be argued that honey can not compete with sugar at the low price of the latter, I reply that it is true, and that honey never will compete with sugar, even at the same price, only to a limited degree. Bakers and manufacturers might use more if cheaper, and to a certain extent honey might take the place of syrups; but if we depend on realizing the millenium of our hopes in our generation, that is, the time when honey shall be a staple article in every family, and brought home from the grocery as regularly as sugar, we shall be disappointed.

There is no use to deny the fact that honey is a luxury. It isn't used in one family in a hundred to the extent that sugar is. It can not take the place of sugar in the culinary art as practiced in our time. We must not sell it at the price of sugar. A fine article of honey can no more be compared with sugar than the best home-made butter with oleomargarine. People want butter because they like it best, because it is more healthful, and because they detest a fraud. Oleo doesn't supply the place of good butter. The comparison is not strictly true, but people buy honey because it fills a want not supplied by sugar. If we produce genuine "gilt-edged" honey, and can get it before the people in perfect condition, they will not ask that it be sold for the price of sugar. The consumption of sugar in this country is so much greater than the home supply, that it was public policy to admit it free. Then to prevent the extinguishment of the cane-sugar industry, which is confined to a comparatively small area in the South, and to encourage the beet-sugar industry, which is yet in its infancy, a bounty of 2 cts. per pound is given by the government for all home-made sugar of a certain standard. As a honey-producing country we are not in the same condition. We produce honey nearly everywhere in all this immense heritage, but we do not yet produce enough to supply the people if it could be properly distributed. Our only competitor in comb honey is Canada, and we have not thought it necessary to put a tariff on that. I presume they find a better market at home and in the mother country for their surplus.

The question, then, narrows down to this: Do we need a bounty, other than what we now have in the protective tariff on extracted honey? I doubt it, but yet am willing to listen to arguments in favor of an increase.

Forest City, Iowa. EUGENE SECOR.

[We stated in our last issue that we would have to declare the discussion on bounties at an end; but the foregoing, coming from the source it does, and covering the whole matter of bounties so fairly and well, very fittingly closes up the discussion, and we are glad therefore to publish it.]

ABSORBENTS, NOT SEALED COVERS.

C. P. DADANT FURNISHES SOME GOOD ARGUMENTS FOR THE FORMER.

Friend Ernest:—As I notice by your editorial that you are becoming satisfied in your mind that sealed air-tight covers and no absorbents are necessary for successful wintering, I beg leave to give you our experience on the subject.

In the winter of 1878 we had very long protracted cold weather, lasting some six weeks, without a day warm enough for the bees to fly. At that time we had been making chaff hives, one story, with chaff cushion over the brood-chamber, and we had some 80 colonies located in this way, scattered in two or three of our different apiaries, the rest of our bees being in Langstroth-Quinby hive that we use. We then believed in a warm, air-tight covering over the brood-chamber. We used oilcloths over the frames, and leaves in the cap, wherever no chaff cushion was used.

It happened that a number of our oilcloths were rather worn, and had holes in them gnawed by the bees, while others were new; but all these cloths were otherwise air-tight, having been covered with propolis, and glued tight by the bees as customary. Now for the result. When a warm day came we found that all the hives that had air-tight cloths without holes were in a pitiful condition, the thick frost having thawed, and wet the bees so that most of them looked as though they had been in a bath. They would crawl out and die. In a few days the hives were empty and dity. Wherever the cloths had holes the moisture had ascended into the chaff or leaves, and the bees were dry. Those hives which had the worst cloth covers were the driest. It was so uniform, that, after opening a number of hives, we could tell before raising the cloth what would be the condition of the bees. Remember, this was in a season when all the hives, without exception, were suffering from diarrhea, and when a number of colonies had died outright from starvation, being unable to reach the honey placed on the side of the cluster. But we were shown plainly, that, when the combs were closely covered with absorbing material that allowed the moisture to pass out without losing the heat, the ultimate result was a clean hive, dry combs, and healthier bees. True, you will find plenty of seasons when a tight covering will do no harm; and it is an accepted rule among old bee-keepers that a hive which shows running water at the entrance during a middling cold day is sure to be healthy. In this case the condensation is not in great amount: it is only in the corners, away from the cluster, and the least rise in temperatrue allows it to melt and pass out. But let a very hard, protracted winter come, the frost which has formed in the corners gains steadily till it reaches the entire top of the hive; the dead bees obstruct the floor and prevent the draining of what does thaw. Then in milder days when the temperature is still too cold for a flight, the thawing frost wets a part of the bees, makes them restless, and the colony is doomed if the weather turns cold again. Perhaps we are mistaken in our conclusions; perhaps there are other things to be taken into consideration; but we have passed through several other winters since the date mentioned—those of 1880 and 1884, and we have only strengthened our belief by all the remarks that we have made. Even in such a winter as the present, there are people whose bees suffer from this very cause, wet combs, and always in instances where the ceiling is air and water tight. Facts are stubborn things, for they overthrow some of the best constructed arguments.

Now allow me to quote an authority to whom we all go back occasionally, and who was acknowledged one of the most careful observers in his time—father Langstroth.

> In March, 1856, I lost some of my best colonies under the following circumstances: The winter had been intensely cold, and the hives, having no upward ventilation, were filled with frost, and, in some instances, the ice on their glass sides was nearly a quarter of an inch thick. A few days of mild weather, in which the frost began to thaw, were followed by a temperature below zero, accompanied by furious winds; and in many of the hives, the bees which were still wet from the thaw were frozen together in an almost solid mass.

We are often wiser than our elders, and so were we on this subject; for although we had read the above passage we were not convinced of its importance till we bought our experience by actual losses. These are the facts that I was about to give you last December, face to face in your apiary, when I was interrupted by that miserable photographer. Please don't make up your mind that I am wrong till we have another hard winter, and you try my way, comparatively with yours on a large scale. Hard winters are oftener found in the bee-keeper's yard than millions in his pocket. C. P. Dadant.

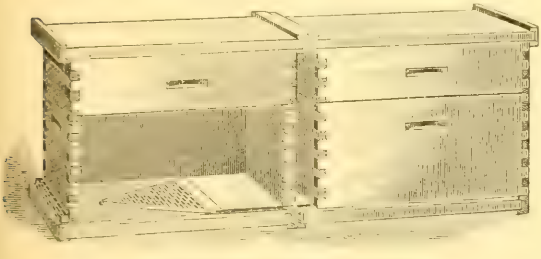
Hamilton, Ill., Mar. 5.

[Facts are stubborn things, and we must yet wait and compare results. While nearly all the testimony is in favor of sealed covers as against absorbents, perhaps we had better go slow. We are still open to conviction either way.]

PRATT'S SELF-HIVER.

AN IMPROVEMENT OVER ALL OTHERS.

I am one of those bee-keepers who believe that the matter of swarming will be solved through some controlling device, such as an automatic hiver. The most serious drawback in working a large number of colonies for comb honey in several different yards is the inability to control swarming. It has long been my belief, that, when a large number of colonies are worked in outyards, it would be more profitable to throw the working force of three strong colonies into one hive provided with plenty of storage room and ventilation, so as to decrease the amount of labor and confine the swarming fever to one-third of the colonies, instead of allowing it to prevail throughout the entire yard. I will not attempt to explain a method of procedure along this channel, but will confine myself to the text, and endeavor to show the readers how I have successfully controlled swarming in my own and another yard.



PRATT'S SWARM-HIVER.

Since 1889 I have been experimenting with automatic swarm-hiving devices, and I have at last contrived a plan which I shall guarantee to work with perfect satisfaction in the hands of any bee-keeper. My device is patented, but I trust that will not prejudice the readers of Gleanings against it.

The great trouble with all the swarmers yet brought out is *trapping the queen away from the entrance*, to which the bees have been accustomed to work through. Mr. Dibbern's modification of the Alley swarmer will work about as he says it will. I have tried that plan, and would have adopted it, with Mr. Alley's consent, had I not discovered a surer one.

It is a serious drawback to have one hive rest upon another, besides the amount of machinery required to fit all sizes and styles of hives found in any ordinary yard, to say nothing of the close adjustment necessary, and the expense and bother of so many parts.

By referring to the engraving you will readily see how my swarm-hiving device is attached to one of Mr. Root's Dovetailed hives for illustration. The hive to receive the swarm is placed in front of the colony expected to swarm. The front ends of both bottom-boards are abutted so as to form a continuous passage from the swarming colony through the new hive. A little block is placed into the open space between the two hives, so that the bees can not escape from that way. By covering this space with wire screen, the ventilation of the hives will be sufficient for the strongest colonies.

With this arrangement the bees are forced to go and come through the new hive with their honey and pollen. A triangular zinc bee-escape is now placed on the bottom-board inside the new hive, with its open base close up against the entrance to the colony expected to swarm. This escape is made of perforated zinc, and has a hole at its apex for the queen to escape through. The outside entrance to the new hive is covered with an ordinary excluder, so that the queen can not escape from within the new hive after she passes the zinc escape.

When the swarm issues, the bees rush pell-mell through the zinc escape and empty hive into the air. The queen, on finding she can not get through the zinc at the entrance, will pass down the escape, and is led through the hole in the apex, when she will quickly enter the new hive, where she will be effectually trapped. All the exits to the new hive being covered with excluding zinc, the queen is made a prisoner inside the new hive; and as soon as the bees that have swarmed into the air miss their queen, back they will come to the old entrance, as their instinct dictates, thus automatically hiving themselves in the new hive. A few of the older bees will work back into the parent hive, but the bulk of the swarm will remain with the queen. If empty frames have been inserted they will start at once to build comb and set up housekeeping in the new hive. If left in this position eight or ten days, a large number of young bees that have hatched from the parent colony will work out into the new hive. If the supers were shifted on to the new hive, a considerable quantity of honey would be carried there. The bee-keeper now has the option of increase or not, for there are 13 days before more swarming, which gives him a chance to manipulate the old colony as he sees fit. If he desires increase he can set the new swarm back on the old stand and place the old colony on a new stand, after shaking the bees off one or two combs to give the swarm sufficient strength to store box honey. If he does not desire increase it will do no harm to allow the hives to stand as they are a few days, when he can either cut out all the cells or place the old hive on top of the new one, with a bee-escape or zinc honey-board between, or leave them until a day or two before the young queens hatch, when he can shake off all the bees and place the extra combs around on other hives.

The device will need very little if any attention. The principle employed, I believe, is the correct one; i. e., trapping the queen inside the new hive, and causing the bees to join her by the entrance they have so long been accustomed to going in and out of during their work daily. I need not say that the principle is a new one, and bound to work perfectly when properly arranged. I shall endeavor to make the contrivance as light as possible, so as to be safely and cheaply sent in the mails.

Beverly, Mass., Feb. 9. E. L. Pratt.

[We have all along been a little doubtful of the utility of automatic swarmers; but when Mr. Pratt explained to us the principle of his swarmer by which the bees are automatically caught in a hive, the entrance to which they have long been accustomed, we were interested at once. It is not wise to be certain of any thing we have never tried; but we believe this is a little ahead of, and cheaper than, all the others. Of all other automatic swarmers, the bees are obliged to go with the queen to a strange entrance and a strange hive, and it is owing to this fact that so few bees *remain* in the new lodgings provided for them.]

A BEE-KEEPER IN BAD LUCK.

A LAUGHABLE INCIDENT.

A German bee-journal, *Blætter fur Bienenzucht*, has the following story which has been translated into the French *Revue*, and is good enough, I think, to have an English setting.

C. C. MILLER.

At the apicultural exposition at B., Antony Bumke became the happy possessor of an Italian queen. How he admired it with its eyes of gold and its abdomen of yellow and black rings! In order to take it to his hive, he made a box like a Swedish match-box, only, instead of a wooden cover, he used a cover of paper pierced full of little holes. With the queen he imprisoned four workers. "She'll not be so lonesome," said this sensible young man.

What fine things he promised himself with the progeny of this queen, and with what joy he felt the little box in his trousers pocket! But he must, before taking the train for home, send a telegram to his betrothed and his future mother-in-law, whom he expects to greet for a few moments, as the train passes the second station. Time presses, the train is about to start. The engine whistles, Antony makes rapid strides across the platform, and jumps into the first coach he comes to, the coaches being still of the ancient pattern that contain only a few passengers, these few being locked in by the guard, like so many prisoners. In his headlong haste he stumbles over the extended legs of an old gentleman, and his head strikes forcibly against the sharp knees of a precise-looking spinster, whose fright is expressed by loud cries. With a thousand apologies he succeeds in seating himself, when he overhears the hardly suppressed remark, "The fellow is drunk," a remark which only deepens the blushes of the bashful young man.

He seeks, by his tranquility and upright bearing, to efface this unjust opinion, but, unfortunately, he feels a strong tickling on his right leg. Furtively, Antony feels over the affected part, and in so doing brushes against his next neighbor, a big, Jewish butcher's wife.

"Don't let that happen again," she snapped out.

Antony reddened to the ears anew; but the next instant, with a wild look, he sprang into the air.

"You ought to be ashamed of yourself, to come among decent people in your present condition," said the old gentleman with threatening looks. "Such things ought not to be tolerated. It's an outrage!" he growled from his corner.

At this moment Antony feels anew a violent stinging. Summoning all his courage he bravely plunges his hand into his pocket. Mercy! he is not mistaken; the box was broken, and the cover crushed at the time of his fall when entering the coach, and there is no trace of either queen or workers.

And now that sting in two places! Antony utters a savage cry and leaps anew into the air.

"Mercy on us! He's going crazy," says the butcher's wife.

"Conductor! Conductor! let us out. There's a madman here," cry all the passengers.

Antony Bumke emits piercing yells.

"In the name of heaven! he's going into a furious delirium!" says the spinster.

"Silence! silence!" commands the old gentleman. Then turning to Antony he says, "What's the matter? Tell us."

"I can't stand it any longer," cries Antony, "they are gone—every one of them! they sting—I am stung already! Leave the coach! It is very important that I should be left alone. Otherwise you may all be stung."

"He is mad! An escaped madman! Conductor!" cry all the passengers, beside themselves.

The conductor appears at the window. "Presently, ladies and gentlemen; the train is just going to stop. What! An escaped lunatic? The matter shall be looked into immediately."

The engine shrieks—station N. Full of affright they all precipitate themselves from the coach; and the station-master, informed by the conductor, slowly approaches; and when the passengers are all out but Antony he carefully closes the door, posts himself before the open window, and commences his examination. "So this is an escape. You acknowledge it?"

"Without doubt—certainly; they've all escaped," declares Antony, very much agitated.

"All?" says the station-master. "How many of them were there?"

"Five," says Antony, groaning; "four workers—their loss wasn't much—but the queen is gone too."

"What? A queen? What was she like?" said the station-master in a bantering tone.

"Oh! she had eyes of gold, and the back part of her body was covered with rings of yellow and black."

"Beautiful queen!" said the station-master, laughing. "And what were the others like?"

"Why, just like all workers. One bee is just like another."

"Come, now, keep your thoughts together, young man, and don't go to getting bees in your head again," said the station-master severely.

"I haven't them in my head," said Antony, groaning, "but in—"

"And where then?" said the station-master, laughing.

"In my—in my—pants!" This last word Antony whispered in the ear of his interlocutor. "I had a hole in my pocket—they slipped through it."

"What slipped through?" asked the confused station-master.

"Why, the queen and the four workers."

"Ha! ha! ha! a queen and four workmen in his—ha! ha! ha!" laughed the station-master. "Come, be quiet. What are you crying about still?"

"Oh! oh!" cried Antony; "I can't stand it any longer."

The bell rings. Laughing as he goes, the station-master directs his steps to the telegraph operator to give orders to the next station concerning "the lunatic."

The train is in motion. Antony is alone. He can no longer stand those stings. Rapidly taking his determination, he takes off his pantaloons and approaches the window. Three bees gaily soar aloft into the air, but two stick tightly to the pantaloons. However, they must be got off, and Antony shakes his pantaloons out of the window. "A pleasant journey to you, miserable queen," said he dolorously, when, at that instant, whiz! went the express train by on the other track. It seemed to the poor fellow, more dead than alive, that his head was torn away, but it was only his pantaloons that the express train had carried away triumphantly, and for good.

Antony Bunke stood petrified. It was night in his soul. He remained some time without thought and without —. The muse itself, horrified, veils its face.

Again a whistle, piercing, to make one shiver to the marrow. To Antony it sounds like a funeral-knell. The train stops boldly before a platform filled with people. They are there, his intended, his future mother-in-law, with many of their acquaintances. Ashamed, he hides himself, for the door has just been opened. The conductor appears; he makes a sign, and the station-master approaches with two officers. They seize him.

"He has dressed himself up now," said the conductor, laughing.

"Silence!" said the officer. "Bring a cloak."

The second officer takes off his cloak and puts it on Antony. A struggle ensues, and the miserable youth succeeds in jumping out of the coach. The officer seizes him; he tears away, and the cloak remains in the hands of the officers. A cry escapes from two mouths. Blushing with shame, his intended turns away her head; the future mother-in-law is turned into a pillar of salt. Before their eyes Antony is again seized by his persecutors, and shut in with them in a charitable closed carriage.

By mail the thing ought to have been explained away at a later date. But Antony Bunke never had any further desire to try new races of bees, nor to attend bee-shows, and equally he never revisited his enamorata, for she wrote him that she had no desire to marry a sans-culotte.

Ah, yes; he was a bee-keeper in bad luck.

THE BEE PARALYSIS.

A GERMINAL DISEASE, AND HOW TO CURE IT BY ANTISEPTICS.

Judging from the reports found in the apicultural magazines, we may believe that this disease was quite general throughout the country during the summer of 1891. Practically the same symptoms are described by correspondents as they have written from different localities. The points have been as follows: First, the queens have appeared healthy, and there has been no diminution of egg-laying. Second, the usual attention to brood-rearing upon the part of the colony has been observed. Third, even greater fecundity upon the part of the queen, and greater alacrity among the brood-rearers have been noticed, presumably because the colony was stimulated to greater activity in order that the requisite number of bees might be kept up, in view of the untimely death of many of those newly hatched. Fourth, the death-stricken young bees have had the black and yellow colors very distinctly marked, and a peculiar gloss which is quite unnatural, and have also failed to possess the hairy and plump appearance found in a healthy young bee. Fifth, they died in large numbers, very few within but mostly at the entrances, or just in front of the hive. Sixth, there was universally a peculiar, sour, decaying animal odor, offensive as one opened a hive or brought one of those dead bees to the nostril. Seventh, they gathered honey as expeditiously and well as ever, storing more in the surplus sections than usual, seeming to have a fear to put it in the brood-chamber, and, at the close of the season, after brood-rearing ceased, were found to be in poor condition, perhaps having to be fed.

These are the statements that have been made from time to time in GLEANINGS and other papers during the past year. We observed and tabulated them, for we had the disease to look after among our own bees, and were desirous of information, and anxious to impart what might be reliable to our fellows in the craft. They agree with our own experience during the past season. We had two colonies with this clearly defined and unmistakable malady. We cured one at once by putting all the bees temporarily into another hive, and immersing every frame in a warm weak solution of Lewis' concentrated lye, having washed first the interior of the hive with the same, rinsing all off well with warm water, and wiping and drying in the house. This killed every egg and unsealed larva, but, as far as we were able to discern, the capped brood was unharmed. The proportions we used, and the processes, were as follows: Three ordinary pails of water, as warm as the hand would bear, were put into a tub, and three level teaspoonfuls of the lye, which we previously dissolved in a pint of cold water, and then added. We did the task as quickly as possible, and had all the bees back in the hive within two hours. The queen began at once to lay in the renovated combs, and the colony thrived thenceforth, going into winter quarters in fine condition. To make this report good to date for the benefit of other experimenters and all our fraternity of bee-lovers, we have just been to the cellar and investigated this colony, and find them to-day (Feb. 1) in prime order, the queen still living and full of life. Perhaps we should say that we never noticed any ill effects from the lye-killed larvæ. They were all disposed of by the bees themselves, except a few that we picked out with a small two-tined fork.

After reading about the salt cure, recommended by some apiculturists, we tried it upon the other infected colony by simply putting a layer of salt upon the entrance, so that the bees had to crawl over it to get into the hive, or when making their exit. We think that this test was made too late for us to be sure of its effect, but will say that the disease gradually abated until we thought it was cured. Upon two or three occasions we carefully looked for the queen of this latter colony; but, failing to find her, we supposed she was dead, and put the colony in the cellar with the expectation of getting a new queen in the spring. But recently, to our surprise and gratification, we found her, apparently well and full of vigor.

In both these cases the indications warrant the supposition that the disease does not affect either the usefulness or the life of the queens. Moreover, from the look of a colony of bees, we have been unable to discern any clew to the origin of this dread disease, every ordinary sign of prosperity being visible except the strange death-losses. From the chemically purifying and disinfecting character of lye, as well as salt, we seem to be justified in supposing it to be a bacterial fatality, if their use has proven beneficial. Undoubtedly the lye solution above spoken of would kill every particle of even capped brood in a hive, if the frames were left long in it, or were put back into the hive not having been well rinsed off. Further, lye is one of the strongest of germicides, and, as in human bacterial diseases, the remedy will kill both patient and germs unless administered with caution. The processes above enumerated would also prove very tedious for an extensive apiarist. For this reason we hope it may be verified that common salt alone is a specific, since the material is always easy of access, and quickly and simply used, causing no labor to the bee-keeper, no time, delays, or losses to the bees. If it should prove that salt, either solid or in liquid, is only a palliative and not a specific, we should incline to the belief that bee-keepers can not do better for the coming season, or until something less laborious is discovered, than to use the lye solution here recommended. But on the ground of the germicidal qualifications of lye, we will venture to say that other chemicals known to have the same effect upon bacteria and parasites, such as camphor, thymol, creosote, carbolic acid, tar, etc., will cure bee paralysis if proper solutions of them are applied to hives and frames, and all thoroughly cleansed before being given again to the bees. We believe this to be a germ fatality. If opportunity offers the coming season, we shall try some of these, as well as make ourself more certain as to the curative properties of salt. Meanwhile we feel sure of the lye solution, and can recommend it until something better is found. REV. T. C. POTTER.

Cedar Falls, Iowa, Feb. 3.

THE HASTY SUGAR-HONEY MATTER.

WILL NOT THE DISCUSSION OF ADULTERATION BE EQUALLY HARMFUL?

Friend Ernest:—I wish to thank you for the very fair manner in which you criticise the course of the *Review* in admitting the Hasty article on the feeding of sugar to produce comb honey. Surely, nothing could be fairer than your treatment of the subject; but, with your permission, I should like to call attention to what *seems* like an inconsistency in your course. In the very same issue you publish an article from Mr. Byron Walker, in which he states that glucose can be bought for only two cents a pound, and explains the ease with which honey adulterated with it can be sold. Have you no fears that dishonest people will be led into adulteration by thus explaining how easily the matter may be accomplished? You may say that you mention the practice only to condemn. True. But condemnation does not deter dishonest men from doing wrong. If anybody can *do* any thing to stop adulteration, I am with him hand and glove (I am glad to see you intimate that *you* are going to *do* something); but to be criticised for giving an article explaining how a man might honestly make a profit out of his bees in a poor season, criticised because dishonest men might deceive people by the same method, and then have my critic turn about and publish an article showing the ease and profit with which honey may be adulterated, seems—well, how does it seem?

I am glad to see, Ernest, that you have so far advanced in this subject that you have had enter your mind the idea of: "Will it pay?" I am also glad to see that you so stoutly maintain that, while Bro. Hasty and myself may be lacking in good judgment, we are *honest.* But the Hasty article has been published; it is beyond recall; the cat is out of the bag; there is no use of attempting to crowd her back in; in other words, let us lay aside all prejudice and preconceived notions upon the subject. So far there has been simply "holy horror" at the ideas advanced by friend Hasty. No one has seemed to give the matter a sober second thought. We are so largely creatures of education, that, when any one brings up something contrary to our established views and methods, we are shocked. In the Dark Ages men were tortured and burned at the stake because they were heretics. The very ideas that were then heresy are now popular. This may be a strong illustration, but I think it a fair one. The time may come (mind, I don't say it *will*) when sugar-honey will be an article of commerce. I am willing to admit that the world is not yet ready for it, but the time *may* come. When it was first proposed to use foundation in surplus honey, what a hue and cry there was raised against it! "It was not the natural comb;" "it filled the consumer's mouth with wax;" "it would *ruin* the honey market." It proved to be the "foundation" upon which rested successful comb-honey production. Hence, I say, don't be too hasty in your judgment upon new ideas.

Flint, Mich., Mar. 5. W. Z. HUTCHINSON.

[It is a great pleasure to deal in discussion with such a fair and candid man as our brother-editor Mr. Hutchinson. Well, about that Byron Walker article. It may be that we have been doing just what we had been condemning in another; but it occurs to us that there is a distinction between the Byron Walker article and that of Mr. Hasty. The former calls attention to a practice that is *already in existence*, and we gave publicity to it for the purpose of letting bee-keepers know the real facts in order that they might unitedly combat the evil. The Hasty article proposed something that was not yet in existence, and which at most was a matter of experiment; that is, it was exceedingly doubtful as to whether the practice could be made to pay. While the article of Mr. Hasty *might* do damage, the probabilities are that it will not. Bee-keepers are too honest to make a bad use of it, even if feasible, and we have more than once had occasion to refer to the fact that our industry is made up, as a general rule, of square men. Dr. Miller has a Straw in this issue which points in the same direction.]

WAX SECRETION.

MR. FRANCE ARGUES THAT THE OLD BEES AND NOT THE YOUNG DO THE MOST OF IT.

I wish to make a few remarks about some replies of Mr. Doolittle and Mr. Hasty in regard to an article of mine in the Oct. 1st GLEANINGS, about wax secretion, etc. Mr. D. remarks that I say that I hived a fair-sized swarm. It was just that, and nothing more—at any rate, it came from a hive of 16 L. frames. My home yard is all in L.-frame hives, 8 frames to each set. I work them during the extracting season three stories high; but this swarm came out before I got the third set of combs on. There was not over a peck measure full of bees to start with; and a three-story L. hive with 8 frames in a set is not so very large a place for a peck of bees in hot weather. It is only four combs more than a two-story ten-frame hive. But, be that as it may, 45 days would come around just as soon for a large swarm as for a small one.

As for the young bees secreting all the wax, I am satisfied that it is a mistaken notion. I believe that bees will secrete wax as long as they live; in fact, I am of the opinion that the old secrete more wax than the young ones. In the first place, in order to secrete wax the bees have to stay at home with their sacs full of honey, that wax secretion may go on. Now, in all animated nature is it the old or young that lie around idle? Young children, and all young living things are apt to get out as early as they can, and exercise themselves; and would a young bee be contented to stay in the house during its youth and do housework? I can not believe it. I believe they go out as soon as they are able to do so. They want to go out and see the world—it's natural. On the other hand, the old bees, like other old folks, would be more inclined to stay at home and do the housework. I simply throw these thoughts out as a suggestion. Who will prove me wrong?

As for Mr. Hasty's remarks, they cover about the same grounds that Mr. D. does, except the possibility of some stray swarm joining the experimental colony. I think Mr. Hasty or any other observing bee-man would quickly discover any thing of that kind if it should happen. But Mr. H. is wrong in his conjectures about the failure of the honey-flow soon after the swarm was hived. The swarm was hived June 10; the honey was ample until July 20, when the basswood gave out. At that time I gave the bees in pepperbox feeders 6 lbs. of honey, and kept honey in the feeders all the time after that date. Aug. 24 I took away brood for the last time, and then let them go as they pleased and hatch brood. Of course, it must have been about the 14th of September before any brood would hatch. About that time I fixed my yard for winter, and there were a few bees there yet, and some few hatching. How long they held out I don't know, as I did not look again.

Now, my friends, if life is spared until next summer I mean to try some more experiments; and I should like to have others do the same. Let us learn all we can, and let each one prove for himself any point that he or she is interested in. We have 20 acres of land, shaped about like a brick. Now, as far as possible from the bee-yard, and from each other, as I can, I intend to place two or three hives to experiment with. Let others who can, try for themselves, if they are interested in such matters.

Platteville, Wis., Jan. 28. E. FRANCE.

LADIES' CONVERSAZIONE.

PLANTING USEFUL VS. BAD WEEDS FOR BEES.

If I were a man, and owned a farm, I think I would plant for bees if I had as many as 50 or 100 colonies. Mr. Axtell says it does not pay; but I believe it would pay—not so much in the amount of surplus stored from such flowers, but in the good it would do the colonies in keeping them thrifty and built up between the honey-harvests. I would give a little time to it each year, and see to it that it was done right. If I owned a large farm, and had plenty of ground to spare, I would set apart an acre or more for such purpose; but if I could thoroughly till what I had I would utilize the waste lands, the fence-corners, and next to the hedges. I would not send a hand out and have high-priced seed scattered along the roadsides, in the stiff sods, nor along the fences that are already overgrown with weeds, as I should not expect it would thus pay; but I would take the spade and hoe, and clean out the fence-corners, and plant such seeds as are tried and do well in each locality—such bee-plants as will hold their own after being planted—perennials that will blossom each year at a time when the clovers or other farm crops are not in blossom. I would hoe out the useless weeds close to the hedges or fences, where they can not be cultivated for farm crops. I would plant such seeds as catnip, Simpson plant, hoarhound, pleurisy-root, sweet clover, etc. How much better to grow such plants than so many useless weeds that yield no honey, and are a nuisance to the farmer! I would have a regular string of flowers all around my farm, and near the cross-fences besides. Some argue that weeds thus grown would not be good for the fence or hedge; but they could not be worse than useless weeds or the grasses that grow in the cultivated fields next to the fences, that animals can not reach to eat off. I would not sow bee-plants along the fences of neighbors who would object to such plants, or who annually mow down the weeds in front of their premises. There are many neighbors who are so accommodating as to aid a brother bee-keeper by giving consent to having such plants as sweet clover sown along the roadsides, as it is a beautiful plant, both in the foliage and blossom, and is much more sightly than many of the weeds often seen growing along the roads, and which furnish nothing to beast or bee.

Down near the timber, near where our out-apiary is located, are large patches of burdock and Canada thistles, both in the fields and along the roadsides. How much better to destroy such plants, and raise honey-plants that are not such noxious weeds! I can advise, but I can not practice the above, though I believe it would pay largely, both to bee-keepers and to the farmers.

LACK OF VENTILATION FOR CELLAR WINTERING; HONEY-DEW, AND ITS EFFECTS IN THE CELLAR.

In GLEANINGS, page 133, you print my article about our bees being so uneasy. We did have to take out another cellar window that was plastered up, and it was surprising how soon they quieted down. We can see no difference in the number of dead bees swept up in front of the hives wintering on honey-dew, and those wintering on sugar syrup. The bees are more quiet than they were the fore part of the winter, but they throw out twice the dead bees they have some other winters; but they show no signs of dysentry on the fronts of their hives. I was looking this morning, and saw no hives thus specked. Those wintered out of doors have had several good flights during the winter. Mr. Tilly, who has 30 colonies, and winters outdoors, says that there are but few dead bees in front of his hives, and his bees flew as if they were strong, a few days since. MRS. L. C. AXTELL.

Roseville, Ill., Feb. 20.

[We are rapidly coming to the conclusion that bees need more ventilation in the cellar than many suppose. We notice that there is less flying out in proportion to the number of colonies when there is a small number in the cellar than when there are many. High temperature may have some effect; but, usually, high temperature is accompanied by a lack of circulation in the air, and hence the result is impure air, and restlessness on the part of the bees.]

A KIND OF FIXED-DISTANCE HIVE THAT IS NOT OF THE RIGHT SORT.

I wish some of the advocates of "fixed distances" and "handling hives instead of frames" had some hives I was obliged to use last year. I knew I didn't want them, as soon as I saw them, but had to have something, and they were all I could get at the time. The ends of frames, instead of resting on a tin rabbet, fit into a notched piece of wood, and another notched piece across the bottom of the hive holds the bottom of the frames tight. I could get along with them while the hives were new, by handling the frames over quite often; but I tell you, those hives have fixed distance and no mistake. I believe they would stay fixed, too, if the hives were rolled over and over down hill for half a mile. They are altogether too "fixed" to suit me; for, like Mrs. Atchley in *Nebraska Bee-keeper*, I don't care about "going down the ladder."

I am sometimes asked why I am a bee-keeper. Well, it was neither from choice nor because of necessity, but the result of what most people would call "a bad bargain." But as "all things work together for good," I suppose it was not an accident, after all. Perhaps I'll tell the story some time in the future.

MRS. A. L. HULLENBECK.

Millard, Neb., Feb. 17.

[There are some kinds of fixed distances that are positively intolerable, and such a kind as you describe is one of that sort, as we know from a brief experience; but there are other kinds that are positively delightful.]

HIGH-PRESSURE GARDENING.

BY A. I. ROOT.

THE TOMATO INDUSTRY OF CRYSTAL SPRINGS, MISS.

CLOTH INSTEAD OF GLASS FOR COLD-FRAMES.

On the morning of Feb. 27, 1892, I opened my eyes in a pleasant room in the hospitable home of J. W. Day, the author of the book on tomato culture in the South. Brother Day soon came in with an armful of long pine kindling, and proceeded to build such a nice big fire in the spacious fireplace that I commenced a remonstrance at the waste of so much nice fuel, solely for *me* to dress by. But he replied he had more than he wanted or could get rid of; and, to tell the truth, he has pine timber by the *hundred acres*. Breakfast for a family of eight children was, like the fuel, in great *abundance* and of excellent *quality*. I never ate any canned peaches before equal to friend Day's; and when I found he had *400 acres* of young peach-trees, I felt in a hurry to get out to see *them* as well as the tomatoes. In coming into Crystal Springs the day before, I noted the long canvas-covered cold-frames that began to dot the fields with their long strips of white, even when we were miles away from Crystal Springs. The exceeding whiteness of the cloth is explained by the fact that a great part of them are covered with *new* white cloth, for it is only since friend Day's venture has proved a success that almost every one around him has decided to go into it more or less. It is exactly like the lettuce business around friend Davis' at Grand Rapids, Mich. Well, we are having a great lot of pictures made, illustrating this new industry; but as they will make my description too late for this season I am going to tell you in advance how to make a cloth cold-frame to protect tomato and other plants after they are transplanted the first time from the seed-bed.

The cloth, which is rather thick stout cotton, is used in the place of glass; but as there was quite a frost on the morning I have described, the beds had all been covered the night before with pine straw and forest-leaves spread evenly over the canvas cover. Friend Day has over a mile in length, altogether, of these beds, and each one is double width, taking cloth 2½ yards wide on each side. Such frames have been in use more or less for some years back in different localities; but, if I am correct, friend D. first used the pole to roll the cloth on. I saw one of his men roll up the canvas *alone*, on a bed *150 feet long*.

I need not tell you of the immense saving of time and strength, compared with handling glazed sash. It is true, cloth does not give the protection nor the heat that sash does; but by taking a little more time one can start seeds of even tomatoes and egg and *pepper* plants under cloth. Friend Day has perhaps a hundred glazed sash in use, side by side with glass, so he knows all about it. All the heat used in starting the seeds, in the vicinity of Crystal Springs, is obtained by flues under ground, and burning wood. A simple trench, or two trenches, are dug in the ground, and the seed-bed made over them. Of course, the trench is made on an incline, one foot rise in 20 feet length. The trench is covered with brick, flat stones, or large tile may be used. Pine wood furnishes the heat; and after firing all day, the ground gets so hot (and retains the heat) that your plants are secure from harm during even the coldest night, without any firing during the night-time. Where the firing is done, the opening may be 16 inches across; but it is gradually contracted until it reaches the bottom of the chimney, when it is only about 8 inches across. The chimney is only a square wooden box, say 8 x 10 inches inside, and 8 or 10 feet long. Such a flue will give heat for a bed 40 or 50 feet long. The earth over the flue is 2 feet deep at the *furnace* end, but only 6 inches deep at the *chimney* end. In making the flue, if you arch over with brick, use something similar to a nail-keg to arch over on, sliding it along as you proceed. You can use glass or cloth over this bed as you choose. Of course, glass will give more heat from the sun, and will keep out more frost; but if you commence a little earlier you can get just as good plants by using cloth. I saw plants raised under glass and under cloth, and the latter were every bit as good. Of course, you will have to take more pains in covering the cloth with leaves or straw during very cold spells. Cloth frames have more slant than glass usually does, for the cloth cover is expected to carry off all the rain.

One of the strong points in friend Day's management is to keep the ground *dry*. I could hardly believe he was right until I saw beautiful plants in all stages that had never been watered *at all*. You see, the cloth holds the moisture that rises up through the mellow soil, and at the same time it does not permit the sun to heat up and scorch as the glass does. Friend D. never gives his plants more than one watering if he can help it; and that one is in the *cold-frames*, a week or ten days before they go out to the field. Then they are watered until the ground is soaked. If a rain comes about this time, he prefers it to any artificial watering. Only the seed-beds or *hot*-beds require flues for heat. Now for

THE CLOTH COLD-FRAMES.

This is the great feature of this paper. It is, in my opinion, one of the great inventions of the age. It may be *single* width or *double* width, as I have stated; but the slant in either case should be so as to have a pitch of about 1½ feet in a bed 6 feet wide. The cloth is securely fastened at the upper edge, and the pole on which it is rolled is securely attached to the lower edge. This pole hangs over the lower edge, and holds the cloth down tight to the edge of the one-foot plank that is put around the bed. Strips 1x3 inches are put in like rafters every six feet to hold up the cloth, but they are movable, so as to take them out of the way when desired. To keep out frost, the whole bed must be air-tight, or as near as may be, and the gable ends are therefore held tight by temporary strips, or by strings sewed in at intervals, and fastened to nails driven partly in. To keep out water, make a ditch with outlet, clear around the whole outside. In order that the ground may be cheaply and thoroughly fined up before a crop is put into the bed, the gable ends may be removable, so the horse and cultivator may be run back and forth until all is fine and mellow. Now, here is a bright idea I did not get hold of at first. As every plant is to be lifted from the cold-frame with a square of dirt adhering to its roots, and thus carried to the field, we can not afford to have the field a great way off; therefore the bed *itself* is located in the middle of the field where the tomatoes are to be set. The plants are spaced accurately in the cold-frame, about 5 inches apart. This is done with a marker which looks like the head of a common rake, only it is 5 feet long, and the teeth are 5 inches apart. When the plants are as large as they should be, a butcher-knife is run between the rows, so as to cut out square sods, as it were, a plant being in the center of each sod. But I will tell you more about this later on. I have told enough so you can go at work at once making cloth cold-frames for any of your crops. They will solve the problem as to how we may most cheaply save our valuable early crops from frost. You can use them for early asparagus, cabbage-plants, celery-plants, egg-plants, cauliflower, or any kind of plants that may be wanted; and in many localities they will pay well for early potatoes, wax beans, early beets, etc. I can not learn that they have been used for forcing strawberries, but they would surely prove a perfect remedy for frost in the spring; and after frost is over they are just the thing for melons, cucumbers, etc. In fact, they have been a good deal used for this purpose. When they are located in the middle of the field for tomatoes and such crops, the whole thing is taken apart and moved up by the fence until the next year. Enough tomatoes are left where it stood to get a small advance crop of *extra early*.

Now, this is not conjecture and theory, but it is an account of a great industry that has been going on and developing for years; and I am sure it will interest and profit hundreds of our readers, north, south, east, and west. The book, with illustrations, will be issued during the coming season.

THE PRIZETAKER AND SPANISH KING ONION.

Are these two one and the same thing? Quite a few leading seedsmen, including Johnson & Stokes, who first introduced the Spanish King, declare they are the same, while others, including William Henry Maule, say they are not. One friend writes us that the Prizetaker is a straw-colored onion approaching red, while the Spanish King (or Yellow Rocca) is a yellow one. By the way, how much difference is there between straw color and yellow? I think, friends, that, no matter where you get your seed, or whether you buy Spanish King or Prizetaker, you will find in every field a few onions of red and white both, as well as yellow. I am inclined to think they are sports. Whether these sports can be bred out or not is a question. You will also find similar sports in regard to shape. If the seed is carefully raised from large yellow round onions, so firm and hard they have kept over winter all right, there will be a chance of breeding out these sports, and there is a big opening for some enterprising seedsman, or anybody else, who will take the pains to do this. If there is a man among our readers who can truthfully say he raised the seed himself, from selected onions, during the season of 1892, he can get a big price for his carefully bred selected seed in the spring of 1893. Our friend March gave me some important facts in regard to this matter of seed-raising. It is not at all difficult to get extra nice seed; but it takes more care and patience than most people are willing to give, especially after they have got a big business established. We have some onions saved, and are going to plant them ourselves. Who else will help? Our experiment stations are doing a good work in this very line; and, if I am correct, our Ohio station have decided they could see no essential difference between the Prizetaker and the Spanish King, although they did decide that the seed purchased from *some dealers*, called Prizetaker, was superior to that bought of certain *other* dealers called Spanish King. I wish friend Green would give us a few words on the subject.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

FOUL BROOD IN YORK, NEBRASKA; REPLY TO ELMER TODD; THE DISEASE NOT RAMPANT.

In GLEANINGS, Feb. 15, p. 133, I see an article on foul brood in Nebraska, signed by Elmer Todd. Regarding the subject-matter of the article, we wish to say to Mr. Todd, or any one else, that it is an undisputed fact that there are cases of foul brood in this vicinity; but to the extent that he claims, *it is not a fact*. We have a society here, and one of the express purposes of the organization was to get a unity of action regarding this very disease. To our membership Mr. Todd has often been invited, but will not unite with us, preferring to stand aloof and growl. If it is true, as he says, that rotten combs were thrown in the streets of the city last summer, instead of picking them up and carrying them home, and using them in his own hives, as he admitted to me he did do the summer previous, why did he not report the case to our county bee-inspector, who has been working carefully but effectually to prevent that kind of work, and is stamping out the disease wherever he finds it?

Referring to the catalogue, we suppose he has reference to that of S. C. Gorham, a supply-dealer of York. We printed that catalogue; and before that offer was made, Mr. Gorham said to us: "If he got bees in exchange he could use them in his own apiary; and as to supplying his customers, to my certain knowledge he has arrangements for buying to fill orders *where there is no foul brood*." Mr. Gorham is an old bee-keeper, and a man of principle and honor, and we do not think he would sell any thing to customers from his own yard or this vicinity, knowing that foul brood existed here, and his customers need have no fears; and for one who had little if any knowledge of bees, and never kept any himself until the last two years, and who never goes far from home, or never attends the meetings of bee-keepers, either at home or in the State, to make the broad assertion he does in the published article is unjust and injurious to those who are trying to do the very thing he complains of not being done, but does not help to do.

I hope you will give this as prominent a place as you did Mr. Todd's article, as I think he tries to create a false impression of things here, and injure the trade of those engaged in business here, but which *he does not patronize*.

L. D. STILSON, *Ed. Neb. Bee-keeper*.

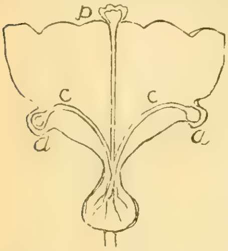
York, Neb., Feb. 22.

[We are glad to give place to the above, as we would not willingly do an injustice to the bee-keepers of Nebraska. We have no doubt that Mr. Stilson, as editor of the *Nebraska Bee-keeper* (an excellent bee-paper, by the way), is in a position to know the facts.]

POISONOUS HONEY; IS THE STORY IN THE A B C OF BEE CULTURE A MYTH?

In the interest of honey-production, every obstacle ought to be removed; and for several years I have been satisfied that there is no such thing as "poison laurel honey." All that I have ever seen written on the subject looked very much to me as if it were the "soldier story," related in A B C, remodeled. Honey sickens many people who are not accustomed to it; and that a gorge of honey (and perhaps plenty of mashed bees) should have had the effects described can readily be imagined. My reasons for this opinion seem to me conclusive.

There are thousands of acres of poison laurel (*Kalmia latifolia*) here, and yet this is a poor honey section. During its bloom the honey-flow is light. No honey here is known to be any thing but healthful. In five years' residence and bee-keeping I have never, in a single instance, seen a bee working upon poison laurel; and, most conclusive of all, the plant makes, as if aware of its poisonous character, provision for its own fertilization. As shown in a cross-section of the flower, it is saucer-shaped, with little pits, or depressions, on the side to retain the end of each stamen with its anthers until the pollen in the latter is ripe. I suppose in the bud the bloom is so folded as to guide the stamen *c* in their growth into the pits *a*; and as the corolla unfolds, these become sprung, as a bow. When the pollen is fully ripened the anthers burst, the stamens are suddenly released, and this miniature and beautiful catapult raises quite a dust for several inches around. I have assisted this result often, and it is certainly a beautiful evidence of design in nature. *I* should take that soldier story out of the A B C, or put this by the side of it. CHAS. T. SWEET.



Swanton, Md., Feb. 16.

[Gently, friend S. Please remember that our correspondent J. Grammer, whose letter appears in the A B C, was a veritable physician residing in Halifax in 1875. He may be there yet for aught I know. During the years that have passed since 1875 we have had considerable correspondence on the subject; but the letter in the A B C book seems to cover the whole ground so fully we thought it not best to put in any more testimony. During my travels I met several times the mountain laurel, and inquired about poison honey. The evidence seems to be that it either yields honey only occasionally, like many other plants, or that the honey is not always poisonous. But a great many instances are on record of honey that affected people in much the same way as described in the A B C book. Before we consent to put your letter beside the one in the A B C book, we should like to hear from others who have had experience with poison honey. The letters need not necessarily be for print, for most bee-keepers would feel a little delicate about advertising the fact that honey from their locality was even *sometimes* poisonous.] A. I. R.

ALUM FOR SNAKE-BITES.

I saw in GLEANINGS, some time last year, that some one recommended alum for snake-bites. In your comments you seemed to doubt it, and said that the bite would probably have got well itself. You also stated that so much alum would be injurious. I have lived in Southwest Texas (where there are more rattlesnakes than in any other place I ever heard of) for 33 years. I have had many cases of snake-bite, both with man and beast. I use nothing but alum, and I never lost a case. I cured one man after he was insensible. If I can give a patient the alum as soon as he is bitten, the place will not swell. You must bear in mind that alum, being an antidote for snake-bite, can do no harm of itself until the poison is overcome. I have never seen nor heard of any bad effects. If this should save some person's or animal's life I shall be well paid for writing it.

Japonica, Tex., Feb. 3. JOHN VINING.

BIG RESULTS FROM TWO COLONIES.

In Southern Kansas bees have wintered finely. To date there have been almost no losses at all. We have had a favorable winter for them here. Bees that were out in the yard have been flying a little nearly every week this winter. To-day, Feb. 26, the bees have been carrying in pollen, reminding us that soon we are to see our young bees in the air. Our climate in the latter part of the summer is too dry for bees to do their best, yet it pays to handle bees even here. Bee-keeping is not my business—I am a minister—and yet two years ago I made $50.00 from two colonies; and last year, a poor year, I made $35 from two colonies. Our honey here comes mostly from the sumac. I am now crowding my bees and will expect them to come into the honey harvest under "a full head of steam."

Yates Center, Kan., Feb. 26. N. V. MOORE.

EVAPORATING HONEY BY STEAM.

I have just read J. A. Green's article, page 88, and wish to inquire whether anybody has ever tried evaporating honey by steam. I can't see why it would not work "just splendid" to run the raw honey through an evaporator with a transverse current over a steam-chest. I once evaporated some in a tin can on a cook-stove, and it "took the cake" over any thing that I had that season, and remained liquid (if that is the correct word, but it was very thick) until the latter part of the winter. But evaporating in that way takes too much time, and requires too constant watching for fear of scorching. With an evaporator, such as suggested above, a constant stream could be run in at one end from a faucet, and the heat would be uniform, so that a uniform article could be turned out without danger of scorching. What do you think of it?

Centerville, Ia., Feb. 9. G. B. REPLOGLE.

[Mr. Thos. Wm. Cowan, of the *British Bee Journal*, constructed an apparatus for evaporating honey by means of hot water; and the apparatus is illustrated and described in the A B C of Bee Culture, under "Extracted Honey." Hot water would be better than steam, because the latter would be liable to scorch or overheat the honey.]

OUTSIDE WINTER CASES, WITH DEAD-AIR SPACE, A SUCCESS.

Long before I ever read any thing about bees, since 1880, I was convinced that bees should be wintered outdoors in unpainted hives, with covers sealed down tight, and that the hives should be protected from the weather by outside cases. I have never found the necessity of any packing between those hives when the outside case is air-tight. This sealed cover was impracticable with the Simplicity and chaff hive. Since 1882 I have been using a hive as made and used by Henry Alley, unpainted, with a cover which always was sealed down in the fall, and I can say that these hives wintered bees each winter since, and never lost any. J. T. FLETCHER.

Clarion, Pa., Feb. 26.

WHY DO QUEENS DIE IN THE SPRING?

I want to ask the following question through GLEANINGS: What is the cause of so many young and prolific queens being lost before the honey-flow in the spring and after the flow in the fall? We have never seen any discussion in any of the bee-journals as to the cause of so much fatality of queens at the above periods. We can readily guess why there are more queenless colonies discovered in the spring than in the fall; viz., because persons do not examine their bees in the fall closely in this respect, consequently many of the spring queenless colonies were queenless in the fall. J. A. GOLDEN.

Reinersville, O., Mar. 1.

[Of course, the rigors of winter must have some effect upon the vitality of bees and queens alike; but aside from this we do not discover that our young queens die more in the spring than at other times.]

BEES' WINGS NOT INJURED BY BEE-ESCAPES.

Referring to the editorial in the last issue of GLEANINGS, mentioning the Porter escape, permit us to say that the objection therein rumored to have been urged against its use is, to our minds, absurd. The springs used in it are smooth on the edges, and everywhere else, and it is not possible for them to injure the wings of the bees. From the letters, etc., inclosed herewith, which we should like you to read and return, and others which we have, we can not think that any Canadian association of bee-keepers ever took such action. Of the more than 5000 escapes sold last year, with the privilege of returning and getting money back after three months' trial, if not satisfactory in every way, not one was returned, nor was a word of complaint received from any one buying them.

Lewistown, Ill., Mar. 5. R. & E. C. PORTER.

[We have read the letters from the Canadians referred to. They all speak highly of the success of the Porter escape.]

INDIANA BEE-KEEPERS.

The names and postoffices of those who have represented the industry at the county and district fairs, and those who are thinking of making an exhibit at the World's Fair, are wanted by a committee, appointed by the Indiana State Bee-keepers' Association. The names are wanted, to be submitted to the proper authorities who will assign the proper space, give needed information, etc. It is hoped that Indiana bee-keepers will take a lively interest in the work, as we have the resources, and there is no reason why we can not make as good a showing as other States. Please send names to Walter S. Pouder, 175 East Walnut St., Indianapolis, Ind.

Committee { E. H. COLLINS.
R. S. RUSSELL.
W. S. POUDER.

MORE PROPOLIZED QUEEN-EXCLUDERS.

You ask if any one has been troubled with bees propolizing the perforated zinc. I have had them propolize the zinc, and I have had them to fill up ¾-inch auger-holes bored in the top of some box hives that I used. If I could overcome that difficulty I would put queen-excluders on all my hives. L. A. DUGGAN.

Cuthbert, Ga., Mar. 7.

EXTRACTING HONEY BY STEAM, ETC.

Will Mr. Osburn please tell us how one man can handle a cart containing 80 combs of honey? From 30 to 40 are as many as I can handle. They average something over 7 lbs., consequently his 80 combs would weigh 560 lbs. or more. With an ordinary cart, such work is impossible.

Gamma, Mo., Feb. 19. THOS. A. ANDERSON.

I have 39 colonies at present, and the leather-colored Italians take the lead in honey-production. W. R. CLOVER.

Clinton, Ind., Feb. 6.

[The fact is, as we have often repeated, the leather-colored Italians are bred for business and not for yellow bands. Your experience agrees with that of many others.]

PREVENTING AFTER-SWARMS A LA DADANT.

As you wanted to hear from those that returned after-swarms *a la* Dadant, I will say they generally come out again, some as often as three different times. But after I took to caging the queen out of the after-swarm three or four days before I let her loose with them, I had no more trouble with after-swarms. Bees seem to have wintered well so far. I have not lost any up to date.

Marshfield, Mo., Mar. 1. J. D. WHITTENBURG.

NOTES OF TRAVEL

FROM A. I. ROOT.

WILSON'S PEAK.

When I first visited Pasadena with friend Woodberry he pointed out to me Wilson's Peak, with the trail plainly visible up its rugged sides, and told me that, before I left the vicinity, I must be *sure* to make the ascent. I did not think much about it; but as there were several places in that vicinity where we were to call, I took the matter under consideration. On Friday, the 22d of January, our good friends Farr and Wm. Stevenson met us at the depot, and, with the aid of friends Kirk and Abbott (president of the Southern California Association), we were shown over the magnificent new residence of Prof. Lowe, who obtained such a celebrity during our recent war by his wonderful balloon ascensions—Prof. Lowe the æronaut we used to call him. I think he made about 300 ascensions in all, in the service of the government. From the observatory on the summit of the mansion, we got, by means of a glass, a plain view of the trail, and also a glimpse of the observatory on the summit of the Peak. After finding the spot with the glass we could just define it with the naked eye; but it was a mere speck, about like the head of a pin, and it glistened in the sun like a miniature tin cup. From this time on I began to get the Wilson's Peak *fever*. Somebody said it was two miles to the top; others said it was four; and finally some one who had been up said it was *seven miles*. The livery-stable men said, however, *nine* miles, and wanted $3.00 for a horse and saddle to go up and back. Now, I knew from sad experience that it tires me and uses me up much more to ride a horse than to go on foot—that is, while I have been out of practice for so many years. I inquired whether anybody had ever gone up on foot. A *few* had done it, I was told, and friend Farr said he had gone part way once, and he said he thought he *could* go the whole way. We went to dinner, but I kept every now and then turning my eye to the dull gray mountain as it lay against the northern sky. Friend Farr's folks gave us an extra nice dinner, and I excused myself for eating so much by saying we *might* try to ascend the mountain. Mr. Farr said if we tried it we must start right after dinner; but we first had to take Mrs. Root over to friend Stevenson's, and we had trouble in finding where he lived. Then, although the base of the mountain seemed only about half a mile away, it proved to be *seven* miles. Again, the ground that looked *down* hill toward the mountain was really *up* hill. Furthermore, before we reached the foot the road was stopped by a broken bridge, and so we started to go the rest of the way on foot. It was only a little piece, any way; but the further we walked, the further and rougher the road seemed, until we were on the brink of a cliff that looked next to impassable. While we stood, like Christian in Pilgrim's Progress, some one hailed us from below. It was friend Stevenson with the buggy. He had found the right road, and was calling us to come out of briers and rocks, and get in and ride to the *real* foot of the trail. He made me think of Evangelist in the same book I have mentioned. We really were a *couple* of tired and discouraged pilgrims, I fear, and we were very glad to abandon our dangerous road and get back into the buggy. We certainly had learned to appreciate a smooth path and a regular traveled road.

It was fully three o'clock when he bade us good-by, and we started off. He was to keep the horse and buggy over night, and come back for us at eleven the next day. If we backed out we were to get home some time in the night as best we could.

Please let me digress a little here. As my story is to bear a good deal on this matter of *health* as well as endurance, I want you to bear with me when I tell you of my physical condition at this time. I was scarcely through with the nervous chills. Only a few days before, my strength would often give out suddenly when I had walked less than a mile. My overcoat and fur cap were worn constantly, indoors and out, when everybody else, almost, was in summer clothing; in fact, I had at the time a cold in my head and right ear. Add to this a *bowel* complaint that had annoyed me for nearly two weeks, and you will have a picture of the man who proposed to walk nine miles *on a stretch*, up a mountain. Mrs. Root and the other women-folks declared I must take my overcoat, and that my companion must carry it strapped over his shoulders. However, I threw it back into the buggy, and our only baggage was half a pound of crackers and a nickel's worth of cheese. I was full of excitement, and I rather thought I should hold out. In five minutes we were up so high that the horse and buggy seemed like a kitten and a baby-cart. We called down to the earth below, and told friend S. to bring Mrs. Root in the morning, and come rather early, so that she could climb up a mile or so, to meet us on our return trip. Then we called again to have the Kodak brought also. Then up we went. The trail is nicely graded, one foot in ten, and just wide enough for a horse. Before we get down to business in climbing, however, I wish to say just a word more in the health matter. Friend Farr advised me to take a good big drink of water, for none was to be had on the trail again until we were nearly half way up. I did not drink *any*, however. Please bear with me if I tell you frankly why. I knew if I took a drink, even a small one, I should very soon have to stop on account of my bowel trouble, not only once, but may be several times. I have been more or less troubled in this way all my life. Oh how I have envied people who could at any time drink all the water they wanted! From the valley below, the trail seems to run along the mountain-side almost without any very short crooks or turns; but when right there you are surprised to find almost every rod of the mountain-side cut with canyons made by the water in its course down, and the trail is therefore in and out and around sharp rocky curves and into sharp grooves, so you are first in the sun and then out of it, in sight of the valley and out of sight of it, until the path becomes an ever changing labyrinth. The accompanying picture gives a glimpse of this.*

The horse and buggy soon became a mere speck down below our feet, and it was only by carefully scanning the thin thread that represented the roadway that we could see it at all. About this time the grandeur and sublimity of the landscape spread out before us began to be almost entrancing. I have often tried to think what the earth below must look like to a balloonist, and here it was before me. The mountain, that had seemed so gradual in its ascent, when viewed from the valley before, now seemed to be almost straight down, over the edge of the trail; and it *was* so in reality, for a stone kicked from the path went crashing and rebounding until it almost frightened one to think of the immense distance. Before we had gone a mile I felt amply repaid for all our trouble; and every rod we made, further on, showed some new unfolding of beauty. First the trail took one side of the mountain and then another; sometimes it turned abruptly so your right hand was against the mountain, when it had before been toward the valley. Up, up, *up* we went. The points that had at first seemed so grand were now a mile below, and seemed almost on a level with the valley, while away up above us we could see glimpses of the trail we were destined to tread. The easy ascent was but play to one whose heart was in it, as was mine, and my enthusiasm rose as our pathway did in its windings among the rocky precipices. A pretty white house near an orange-grove stood near the beginning of the trail. Every time we came round so as to bring it in sight we noted how it grew less and less. When half a mile up it seemed too small for folks to live in; next time it looked like two pieces of shingles, one laid across the other. You see, the house had an L to it. Next time it was about like two pieces of a honey-section, and at last a mere white speck without shape. The orange-trees looked like rows of cabbages, and finally the whole orchard was only a speck of green. Higher and *higher!* If one felt dizzy a while ago, how should he feel *now*, at this immense height, with the clouds below him? Finally I began to think I could take a good drink without any danger of harm, for I was perspiring a little all over, and the red blood was tingling to my very fingers' ends. We watched for the water-trough; but we were so busy talking and looking off into the valley we did not know we had passed it until we were half a mile above it. The sun seemed pretty hot, and we were not sorry when the trail changed to the north side, where trees and bushes cut off the sun as well as the view. Then I began to discover I was getting tired. We ate some of our crackers and cheese, and for a time I felt stronger; but before we had reached the half-way point I thought I was used up. We had been on the trail just two hours. I rested; but when we got up again I was so stiff and sore I really felt worse. I managed to go a little more than half way, when I spoke to friend Farr as follows:

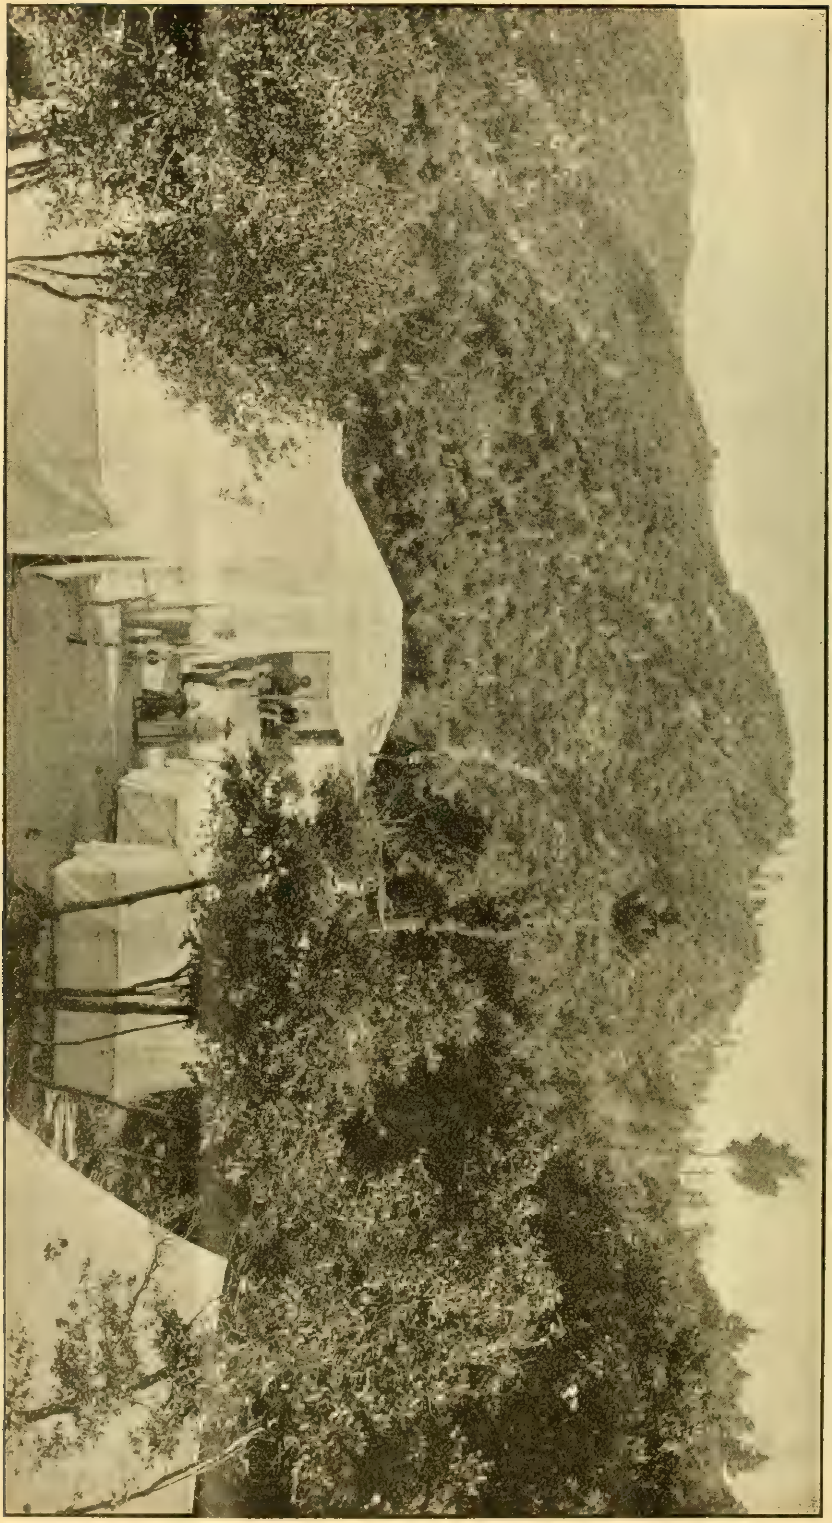
"I *may* be able to hold out until six o'clock; but until *seven*, never."

What *should* I do? It was four miles down and four miles up to any stopping-place. We watched for water, but saw no sign of any, and it would soon be dark. Could we ever tread on this narrow path, so close to such fearful depths, in the night-time? Just about then I must have got what Ernest would call my "second wind." My comrade had just asked if I had any matches. Neither of us had thought of such a thing; but here I was, without an overcoat, and wet with perspiration. He finally fished a broken "lucifer" from one pocket, and our hopes hung on this. I remember thinking I would go a little further, and pretty soon I didn't feel so tired, and started up a brisker walk; then we came out of the pine-trees, and around on that side of the mountain toward the plain again. The picture referred to tells

---

*Our good friend Rambler, on page 197, gives us another very good glimpse of a mountain trail, only his trail is wide enough for a wagon as well as horse.

PINE-TREE POINT, NEAR THE SUMMIT OF MT. WILSON.



CAMP WILSON

part of the story, but it *doesn't* tell, and no picture *can* tell, of that wonderful vision of the world below—the world below the clouds. The following lines tell *something* of what we saw:

> A sweet perfume upon the breeze
> Is borne from ever vernal trees;
> And flowers that, n'er fading, grow
> Where streams of life for ever flow.
>
> O Beulah land! sweet Beulah land!
> As on thy highest mount I stand,
> I look away across the sea
> Where mansions are prepared for me,
> And view the shining glory-shore,
> My heaven, my home for evermore!

We did indeed "look away across the sea," for the ocean had all at once come into view all around us. Mr. Farr said he thought it could not be; but next morning we found it really was the ocean. Down in the valley it was *miles away;* but here it seemed to come almost up to the mountain's foot. Just as we rounded the point (see picture again) darkness set in; and when it was too dark to see plainly, the trail seemed to divide. We took the one that seemed plainest; but after following it in the dark for about a quarter of a mile Mr. F. said he felt sure it was going *down* the mountain, so we felt our way back, and took the other. This went *up* fast enough, *sure;* but it soon became evident it was not *the* trail. We couldn't go back again, so we pushed ahead. I could keep in it only by feeling with my toe, as well as with my hands, and once or twice I really felt so alarmed that I prayed that the great Father above would guide our erring and stumbling footsteps. Very soon after that, this first trail struck the real one, and I tell you I inwardly gave thanks. Up, *up*, UP, we continued to go, until out of the woods we came again, and, oh what a sight met us! Every city for miles around that uses either gas or electric lights sparkled and twinkled into existence in a way that brought strength once more to my tired limbs. Los Angeles was the queen of them all, and then and there she might *well* be called the "queen" of the *earthly* angels. Imagine a thousand twinkling stars, and each star a sun, and the whole of them beneath your feet, and you have it. Pasadena led off as next in radiance, and the rest followed. We were now going steadily round the mountain, and I felt sure that the Mountain Hotel must soon come in sight. By the dim light of the stars we saw a shovel and pick in the trail, up against the bank. They were left, doubtless, by some workman repairing the roadway, and so he couldn't be *very* far away. I have always loved a shovel and pick; but I never saw any tools look so good before. At length, a little in advance, and above our heads, a light met our view that brought from each of us a loud shout of rejoicing. The cut explains it, but you must imagine all the summer tents out of the way, so only the one with the shingle roof (and the stovepipe sticking out of the top) remains.

Our shout was answered by a brisk one from within; and, wasn't there a rejoicing! While the roof is shingles, the sides and doors are cloth. Cloth is cheaper than glass, and lighter to carry up the mountain. With a bright lamp inside, "Camp Wilson" looked very attractive in the night. I was so weary I made for a chair near the great cook-stove; but friend Farr was most anxious about "*water*." Remember, we two had not had a drop for our parched tongues in all that four hours, and up grade eight miles. It was soft spring water, from the summit of the mountain, almost. *160 feet* still higher up. I drank cupful after cupful; and when supper was ready I drank two large cups of coffee, and ate—shall I tell it all? Well, I ate a great lot of pork and beans, ever so many chunks of shortcake, a good lot of honey, and almost half a can of strawberries. I thought the can held almost a gallon; but friend Farr says it was only a quart. I am sure it was *half* a gallon. The sole occupant of Camp Wilson that night was the owner of the shovel and pick; but he is a pretty fair cook, after all. He said they usually had 50 cents a meal, and 50 cents for a bed; but as our supper was cold, and they were out of meat, he would call it a dollar each for supper, breakfast, and lodging. Before I went to bed I drank a lot more of that spring water, and I never had even a *reminder* of that supper of pork and beans, etc.

GLEANINGS IN BEE CULTURE
A Journal Devoted to Bees and Honey and Home Interests
Illustrated Semi-Monthly
36 Pages 7×10
$1.00 Per Year

In the multitude of counselors there is safety.—PR. 11:14.

EIGHT extra pages this issue.

WHO is the editor of the *Canadian Bee Journal?* We hope our old friend D. A. Jones is still at the editorial helm.

OUR subscription-list now numbers 10,125. In spite of the poor honey seasons, we manage to keep above ten thousand.

WE are having quite severe weather this 11th day of March—high winds, and the mercury sporting some of the time very near zero.

AS usual at this time of year we are again flooded with good available matter for publication; but we fear we shall not be able to use all of it.

DR. MILLER says he saw a book on Ernest's desk, on patents. Yes; and if he had rummaged around a little he would have found two or three more. No, we are not going to patent any thing—not even sealed covers, even if we did enjoy the exclusive priority of discovery. The fact is, we like to keep a little posted on the patent question, you know.

DR. MILLER'S Straw against letting bees starve in April is timely. We are now approaching the time of what is sometimes called "springing bees." By the way, it has often been said, and with considerable truth, that it is a good deal harder to "spring" bees than to winter them. Variable weather, that is, warm spells in which brood-rearing gets started, followed by a cold snap in which the brood is killed, is very disastrous, and continued cold weather is far to be preferred.

IN our editorial in the last issue, in regard to adulterating extracted honey, we warned the general public against buying jars of honey (?) containing a piece of comb in it, for the reason that the comb was probably only a delusion and a snare, to give the glucosed mixture the appearance of honesty. We further stated that we did not believe that a single bee-keeper put up his broken-comb honey in that style. We have since learned that there are bee-keepers who put up their honey in just that way; and it is the only way that they can get rid of broken-comb honey at a fair and reasonable price. We have since learned that our friend M. H. Tweed, of Allegeny City, Pa., a bee-keeper and honey-merchant—a man of integrity, honor, and principle—has been putting up pure broken-comb honey in glass jars. We regret that our editorial should reflect in one or two cases on honest bee-keepers, and in another case on our friend Mr. Tweed. His name alone on any kind of package of honey is a perfect guarantee of its purity; and while we believe that adulterated goods are put up in this style, we desire to correct, so far as possible, any injury that may have been done to the business of reputable and reliable men.

In addition to what Ernest has said above, I would suggest that the great trouble in putting up honey in the manner mentioned is the candying of the liquid portion. Either only a little should be put on the market at a time, or something should be done to prevent candying. The venders of this sort of liquid comb honey have excused themselves for using corn syrup, on the ground that it was the only thing that would not candy. A. I. R.

Low prices on dairy products which have prevailed for several seasons, says a correspondent of the *American Agriculturist*, have led many of the dairymen of Central New York to consider the question of engaging in some other branch of farming. The hue and cry is often raised against the low prices of honey, and of the unprofitableness of bee-keeping. If we glance about us we find that other rural industries have similar grievances. As R. L. Taylor said, "Economy in honey production is the sheet anchor of the apiarist's hope." Economy in the production of all kinds of crops should be the watchword of all. If we can not force prices up, the only alternative is to force the cost of production *down*.

ARTIFICIAL COMB HONEY.

I AM sorry that so much space was taken on page 139 in regard to the payment of the $1000 reward. The whole point of the matter is just this: Our card reads, "I will pay $1000 in cash to any person who will tell me where comb honey is manufactured," etc. Now, the thing that was sent us was not comb honey at all. No man, woman, or child on the face of the earth would think of calling it comb honey, neither would the man who made it, if he would consider for a moment; therefore we have nothing to do with it, and there is nothing more to be said about it. You will remember the matter came up because so many were declaring that comb honey *in the market* was not made by the bees, but was manufactured. None has ever been produced. When anybody *does* find comb honey which he thinks was not made by the bees, we should be glad to hear from him. A. I. R.

THE OLD MISSION OF SANTA BARBARA, ETC.

As a rule, our good people here have made very few mistakes in my absence; and even in my fearfully bad writing on Notes of Travel I notice only two places that need correction. On page 135, toward the bottom of the second column, we find this sentence:

"I dreamed of her nights, and while on the streets during the day. If any figure in the least resembled," etc.

It is true, that your humble servant has a very vivid imagination, but I fear he never yet got to dreaming on the streets in the daytime; therefore, when you read the above, please imagine it punctuated as follows:

"I dreamed of her nights; and while on the streets during the day, if any figure in the least resembled," etc.

In our last issue, page 171, near the top of the second column, read "Old Mission" instead of "Old Museum." In fact, the Old Mission would be a rather bad place for a *museum*, for no one of the outside world has for years been permitted to take even the smallest glimpse within that sacred walled garden. A. I. R.

HOME AGAIN.

WE reached Medina March 5: and after meeting so many bee-keepers who had seen hard times on account of short crops, etc., you may be sure I felt a little surprised to see the Home of the Honey-bees booming in every department. Some way or other the boys had started up a bigger trade than we ever had before at this season of the year, and they had contrived so many short cuts in business that I have been rubbing my eyes, and staring around ever since. I hope the kind friends in Florida will overlook the fact that we gave them the "go-by" for the present. We saw so much in California, Arizona, New Mexico, etc., that we really felt as if we hadn't any enthusiasm left for any more wonderful things until we reached home and rested up a little. I had planned writing a great lot of letters to the kind friends who made our visit so pleasant; but, somehow, many things need my attention just now. Shorthand writers and typewriters are crowded to their utmost, and some sick besides, and so I fear that some of you will have to accept the good will for the deed. I want to tell you, however, that Sue and I talk of you by day and dream of you by night. But when she said, while we were in New Orleans, that she would rather see home again just then, than all else that this wide world has to offer, I uttered a devout amen, and we made a "bee-line" for the dear old spot. As I dictate this I can see from the window the men across the way filling the hotbeds and cold-frames with seeds and plants, and we are just going to have a lovely garden, even if I didn't get on hand till March was almost a fourth gone. A. I. R.

"PULLING UP STAKES" AND GOING TO NEW HONEY-FIELDS WITHOUT PROPER INVESTIGATION; THE FOLLY OF SUCH A COURSE.

A FEW days ago a letter came from a correspondent who was influenced some time ago by a highly colored account that appeared in our columns in regard to an alfalfa-field, and was greatly disappointed and chagrined by moving to that much-lauded country, to find that it would have been far better for him if he had stayed where he was. This same correspondent stated further that he sold his home, leased his other property for a term of years, and was compelled to accept his new quarters at a great disadvantage to himself. The climate was insufferably hot, and not congenial to his health. It is the height of folly, and a serious piece of business, to go to a new field without thorough investigation. A correspondent who has given a glowing account of some new field may be perfectly conscientious and honest in his statements; but he may be completely blinded with enthusiasm, and such things are possible. Any one who contemplates selling off his property and moving to a new field should first write to the postmaster for the names of old residents who may be in position to give him the information desired. He might then go himself, without his family, and look over the field, if the results of his inquiries so far justify it. Being on the ground himself, he is then in position to decide, without the enormous expense of moving his whole family or selling all the property he has at home at a sacrifice. As editor of GLEANINGS we take the utmost precaution in having only fair, unbiased accounts of these new fields enter our columns. We should, manifestly, not be doing our duty if we inserted none of these accounts, for journals are intended to disseminate information; and the only thing is for editors and readers alike to go slow.

HOW THE BEES ARE WINTERING AT THE HOME OF THE HONEY-BEES.

LETTERS that are coming in every day seem to show that bees are still wintering remarkably well. Those in our own apiary were never in better condition at this time of year, and we have had an unusually cold and severe winter. You will remember that, late last fall, we stated we were wintering colonies outdoors in various conditions—some of them with sealed covers, some with absorbing cushions, in large chaff hives, in the small one-story chaff hives, and still others in one-story single-walled hives, with an outside winter protecting-case. It is a little funny, but the colonies are all wintering equally well. Those in the large chaff hives are doing no better than those in the single-walled hives with protecting cases, with only a dead-air space, so called, between the two walls. It is funnier still, but the colonies having absorbing cushions, and those having sealed covers, so far as we can examine the latter, are wintering just about alike. But this does not necessarily prove that absorbing cushions are equal to sealed covers. Our winter has been remarkably cold and dry. But wait until we get a mild muggy winter, with the ground reeking with dampness, accompanied by frequent rains. It is then that the sealed covers would assert their superiority. Strange as it may appear, we have lost more colonies outdoors during semi-mild winters than during winters that were severely cold. We have *wintered* the bees nicely so far, and it only remains to be seen how well we shall *spring* them.

"Oh, yes!" some one will ask; "why didn't you try wintering colonies outdoors in single-walled hives, along with the others, without any protection? Perhaps they would have wintered equally well with the rest."

Oh, no! We tried that experiment last winter on 50 colonies, and lost them all. Those having protection *all* wintered. We thought it was useless to throw away any more colonies by trying them without protection. It does not pay.

COST OF PRODUCING HONEY; GRADING HONEY.

FAIR and intelligent discussion, without acrimony, as we believe we have in this issue, brings out many valuable points. While some of the debaters, if we may call them such, have *apparently* stepped beyond the bounds of brotherly kindness in their replies, yet we are very sure there is no ill feeling; and if their words were uttered in convention they would be lighted up by many a comical twinkle of good nature. Quite by accident, the discussion in this issue as it appears on the first pages is handled by the giants in our pursuit—some of the first writers in all beedom. Unfortunately it is a little lopsided, leaving Mr. Doolittle all alone. We desire to have all discussion, so far as it may appear in GLEANINGS, well and evenly balanced; and although Mr. Doolittle is on t'other side of the fence to what we are, we have just learned that one of the "giants" in York State favors Mr. Doolittle's side of the discussion, and we have therefore asked him to write an article for our next issue. We think we shall then have to declare the discussion for the present at an end; and in the meantime it would be pertinent for bee-keepers, who are in position to do so, to keep careful account, so far as they are able, of what it costs them to produce their crop of honey for the ensuing year. The discussion that we have already had on the subject will give plenty of material on which to work.

The subject of grading honey seems to have received already its fair share of attention; and while there may be some points that will pass unnoticed we think best to declare this discussion at an end for the present. The whole subject has been discussed thoroughly and intelligently, and the only thing that remains now is for a national body of bee-keepers to agree upon and recommend a system or systems of grading. It looks now as if it would be impossible for all bee-keepers to agree upon any one schedule. As we intimated in our last issue, we may be obliged to have two and possibly three systems of classification. In this event the bee-keepers of the East will have to formulate a set of rules that will be acceptable to them; so also, in a similar way, the bee-keepers of the Mississippi Valley and Pacific Coast. It may appear that we are disposed to cut off discussions prematurely; but it is better to do so a little too soon than to let them go on issue after issue until everybody is tired and disgusted. There is plenty of other pabulum in the field yet, and we do not wish to wear out any one topic until it is threadbare, and thus defeat the object of real discussion.

LETTING BEES STARVE.

WHILE in California I found several apiaries where the bees were starving. One apiary belonged to quite a young bee-keeper in his A B C class. As he wanted more bees, he had been raising queens and making artificial swarms the fall before, until he had his colonies up to 200 or 300 in number. As the bees fly almost every day in the year in that locality, he rather thought they were getting enough. But just before new honey should begin to come in he lost—how many colonies do you suppose, by starvation? Well, pretty nearly a *hundred*. Then when he went to feeding, either he did not feed enough or they got to robbing, until he was getting pretty nearly discouraged. Less than a mile away I visited another very pretty apiary where every thing was tidy and neat, and even a shade was made over the whole apiary, of stakes, poles, and brush. This shade is a necessity in hot climates, to keep the combs from melting down. They wished me to see whether foul brood was in their apiary or not. Well, I did not find foul brood, but I *did* find bees down on their backs, and giving their last kicks because of starvation. I told my good friend that, if he would give his bees a good big feed, and get them up into thrifty shape, I thought his foul brood would all disappear. Now, this brother has been investing money in queens that produce *five-banded bees*, and he wanted me to look at some of them. I told him I would much rather help him get some feeders, and feed every colony that needed it, before another half-hour had gone by. Another friend told me that his bees were all right in December, but he hadn't looked at them since. This was in March. Now, it may do for a veteran to let his bees alone from December till March; but where the weather is so warm that bees are flying almost every day, I think we had better look them over often, and be sure that they don't starve, or even come pretty *near* starving. Just think of the labor and pains required to make artificial swarms, getting each one with a good queen, the bees taught to protect their hive, and brood-rearing set going so as to give them sufficient force to live through the winter—and after this, kicking it all over by a little lack of attention! Sometimes it needs only half a pound of honey to fetch them through; and if any of you are letting your bees starve while you are sending away for queens that produce five-banded bees, I hope you will turn over and do better. Uncle Amos may come around when you don't expect it, and tell it right out before all the world.

Moral.—Be *sure* your bees are not starving.

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All advertisements intended for this department must not exceed five lines, and you must SAY you want your adv't in this department, or we will not be responsible for errors. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. This department is intended only for bona-fide exchanges. Exchanges for cash or for price lists, or notices offering articles for sale, can not be inserted under this head. For such our regular rates of 20 cts. a line will be charged, and they will be put with the regular advertisements. We can not be responsible for dissatisfaction arising from these "swaps."

I WISH to correspond with some one having Mulborough raspberries for sale. R. ROBINSON,
6d Laclede, Fayette Co., Ill.

Solid GOLD

Around the queen centers our future success in apiculture. A poor queen, like a poor horse, will die on our hands when most needed. Color in either case is immaterial, being simply a matter of choice—my choice is the G. M. Doolittle strain of Italians which is not only the prettiest, but is also far in advance of all other strains, imported Italians not excepted.

I am the owner of the best queens ever produced by Mr. Doolittle; and shall govern myself according to Nature's best way of rearing queens.

Listen to what Mr. Doolittle says: "During the past sixteen years, these bees have been bred with great pains regarding their honey-gathering qualities, my average production of comb honey from each colony for that time having been about 80 lbs. each year, while single colonies have given us as high as 298 to 309 pounds."

My capacity is about 300 nuclei, while my rates are as follows: Virgin queen, 40 cts.; untested, $1.00; tested, $2.00; select tested, $3.00; select tested breeding queen, $4.00.

Special Offer. A select tested breeding queen will be given the one ordering the greatest number of queens during the month of Mar., Apr., May, or June. Orders may be booked now, and the pay sent when the queens are ready.

6d **W. V. MOREHOUSE, Lafayette, Ind.**

SPECIAL NOTICES.

GREINER'S SECOND EDITION OF THE NEW ONION CULTURE.

This is just at hand, and contains 15 more pages than the old edition, and pretty much all that is new in the matter up to date. The author has kindly put several extracts from GLEANINGS in his new edition. The price is the same as before—30 cts. per copy, or 35 if sent by mail. We have a limited number of the first edition, which we will offer for 20 cts., or 25 by mail. The latter contains all the directions that are really important for raising onions on the new plan.

CLOVER SEED.

When our last issue was printed the market on peavine and medium clover was about at its height. It has since declined somewhat, so that we are now able to offer peavine at $8.00 per bushel; $15.50 for 2 bushels; $4 20 for ½ bushel; $2.25 per peck; 18c per lb., bag included. We still have a good supply of alsike seed at the same prices as heretofore—$20.00 for 2 bushels; $10.50 per bushel; $5.40 per ½ bushel; $2.80 per peck; 20c per lb., and at this price it is cheaper to sow than the large clover at above price; that is, for the same money you can seed more acres.

MAPLE SUGAR AND SYRUP.

We have had a splendid trade in these products so far. We have been obliged to delay some orders for second-grade sugar, as the most of that brought in was of the very best quality. With the exception of two or three orders for second grade we have been able to supply orders promptly; and if any of our readers still want either sugar or syrup we can furnish it promptly as follows:

No. 1. Best maple sugar, 9c per lb.
No. 2. Good maple sugar, 8c per lb.

Half a cent less in 50-lb. lots; 1c less in barrel lots of 300 lbs.

Choice maple syrup, $1.00 per gallon; $8.50 for 10 gallons; 80c per gallon in 20-gallon lots or more, all in gallon cans.

PAINT FOR BEE-HIVES.

After much experimentation, and a careful study into the paint question, we offer a mixed paint prepared especially for bee-hives. It will not chalk or flake off, and we guarantee it to be free from adulterants, such as whiting, barytes, lime, and other substitutes that do not add to the enduring qualities of the paint. Our paint is made of strictly pure lead, strictly pure zinc, and genuine French ocher of about equal proportions, mixed in pure linseed oil. It is generally recognized that there is no pigment more permanent than French ocher; and this, combined with zinc and lead, makes a most durable combination. The resultant tint is a pale straw color. Price: Pint, 35c; quart, 60c; half-gallon, $1.00; gallon, $1.75. Half a gallon will cover ten No. 1 Dovetailed hives two coats.

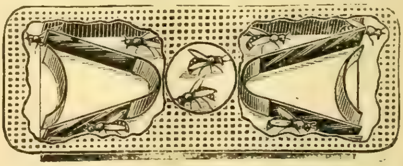
THE NEW ONION CULTURE, AND SELLING ONION-PLANTS.

This seems to be the absorbing topic just now—not only with the catalogue-makers, but dealers in general. The market is almost cleaned out of Prizetaker seed, although we have enough to last for a little while, and hope to be able to get some more. As there is some jangling in regard to whether Prizetaker and Spanish King are one and the same thing or not, we are using at present the Prizetaker seed straight from William Henry Maule himself. I believe, however, that many of you will be better pleased with the White Victoria. It is not so large, but it is so wonderfully handsome; and, by the way, this reminds me there is going to be a tremendous demand for onion-*plants*. I think they can be sent by mail just as safely as cabbage and celery, and we are planting heavily in order to be able to furnish them at the following price—5 cts for 20; 20 cts. per 100; $1.50 per 1000. If wanted by mail, add 5 cts. more for postage on 20 lots; 15 cts. more on 100 lots, and $1.00 on 1000 lots. Perhaps you had better try experiments first by ordering 20; if these reach you all right, and grow without any trouble, then you can try lots of 100 or 1000. They will be fully as hardy as cabbage-plants, I think, and may therefore be set out in the open field at the same time. Of course, onion-plants will be sent out right from the seed-bed; they need not be transplanted as cabbage, celery, tomatoes, etc., are.

OUR NEW BOOK ON TILE-DRAINING.

After many delays it is just about finished; and if you have only a little ditching to do it will certainly pay you to invest the small sum of 40 cents in the book. As an illustration, a few days ago I sent a big strong man who has done ditching, and thought he knew how, out into the lot to dig where I had previously drawn a string for him to go by. It was two or three hours before I got ready to come around and inspect. I found him making little progress in trying to dig the hard clay with a *pick*. I took the spade given him at first, and in five minutes taught him to throw out the dirt a full spade depth almost as fast as he could handle his spade, and this, too, in ground so hard he thought he would have to use the pick. Had he tried to push his tile-spade into the ground with both edges in the clay it would have been impossible, even if he had put his full weight (200 lbs.) on top of the spade; but by putting only one edge in the clay, leaving one edge clear, he managed it easily, and the dirt dropped from his spade without a bit of trouble; whereas, by the old plan the clay would stick to the spade so as to have to be cleared off with a trowel almost every time. The book explains all of this by drawings so plain that any one will "catch on" in an instant. Why, since I have learned how to do it as friend Chamberlain does, I find it just fun to dig in the hardest ground, and the labor isn't severe and exhausting either. This one item, it seems to me, ought to be worth many times the cost of the book; but aside from this the book considers every thing pertaining to tile-draining, brought up to the present date, including all recent improvements. Price 40 cents by mail, postpaid.

Hastings' Lightning Bee-Escape.



Send for sample of Hastings' "Lightning" Bee Escape, and you will be convinced that it is the best and most practical escape yet produced. It will clear the supers in a short space of time (2 to 4 hours), and it is impossible for the bees to clog the passage, as they can not return. Each escape guaranteed as represented. Price, by mail, each, $0.20; by mail, per doz., $2.25. Full directions with each escape. Electrotypes furnished free for dealers' catalogues. Write for discount. 7-12db

HONEY COLUMN.

CITY MARKETS.

PORTLAND. *Honey.* There is very little change to note since our last. Stocks are very light, but the demand is also correspondingly light. Fancy white comb might, however, be forced a cent a pound higher than regular quotations. The weather for past month has been all that apiarists could desire. The hills are covered with wild flowers, and the almond and peach trees are in full bloom. Prices remain as follows: White comb, 1-lb., 15; 2 lb., 14; light amber, 1-lb., 13; 2-lbs., 12. White extracted, 7; light amber, 6½. *Beeswax*, 25.

Mar. 12. LEVY, SPIEGL & CO.,
Portland, Or.

MINNEAPOLIS. *Honey.*—Supply light. There are very few lots of fancy white clover on the market. There is a large quantity of dark honey of both comb and extracted. Fancy white clover, in 1-lb. sections, 16@17; choice, 13@15; dark, 10@12; dark, broken, bad order, 5@7. Extracted, dark, 7; light, 8@9. *Beeswax*, not wanted at any price.

Mar. 14. J. A. SHEA & CO.,
14 & 16 Hennepin Ave., Minneapolis, Minn.

SAN FRANCISCO.—*Honey.* Trade very quiet; stocks of extracted light, and will most likely be consumed before new crop arrives. No inquiry for comb honey whatever, and stocks in excess of demand. We quote: Extracted white, 6@6¼; light amber, 5½@5¾; amber and candied, 5@5¼. Comb honey, 2-lbs., 7@11; 1-lb., 10@11½.

SCHACHT, LEMCKE & STEINER,
Mar. 25. San Francisco, Cal.

ALBANY.—*Honey.*—We have received quite a number of consignments of comb honey recently, with instructions to sell at once; but there is very little demand, and it is difficult to make a sale except at very low prices. Extracted honey in good demand with a very small stock on hand. We quote: White clover, 11@13; mixed, 9@10; buckwheat, 7@8. Extracted, light, 7@8; dark, 6@7. *Beeswax*, 26@28.

Mar. 22. CHAS. MCCULLOCH & CO.,
Albany, N. Y.

NEW YORK. *Honey.* The market for honey is very quiet; very little selling. In fact, there is such a small demand for it just now that we can hardly quote it to the satisfaction of the producer. Fancy, 1-lb., 11@13; 2-lb., 10@12; fair, 1-lb., 9@10; 2-lb. 9@10; buckwheat, 1-lb., 8@9; 2-lb., 7@7½. Extracted honey, clover and basswood, 6½@7. Buckwheat, 5½@6. *Beeswax*, 28@29; in fair demand.

Mar. 23. CHAS. ISRAEL & BRO.,
New York.

MILWAUKEE. *Honey.* The demand for honey has not been as good the past 60 days as was expected, and is now slow. The supply is average, while the common qualities seem to be the largest, and very fine not very large. Quote: Choice 1 lb. sections, 15@16; common, 12@13. Extracted, white, barrels, 7; kegs, 7½; pails, 7½@8. *Beeswax*, wanted, 23@25.

Mar. 21. A. V. BISHOP,
Milwaukee, Wis.

CINCINNATI. *Honey.* No change since our last. Demand is fair for extracted, at 5@8 on arrival. There is a fair demand, and a good supply of comb honey at 13@16 for best white in the jobbing way.

Beeswax is in good demand, at 23@25, for good to choice yellow on arrival. CHAS. F. MUTH,
Mar. 21. Cincinnati, Ohio.

CHICAGO.—*Honey.*—Demand fair for season, and stock of honey is not large; should there come a brisk turn it would clean up the market. Choice white brings 15c, and fancy 16; dark to black is not salable at any certain figure. Extracted, 6@7@8, according to the body and flavor. *Beeswax*, 27.

R. A. BURNETT,
Mar. 21. 161 So. Water St., Chicago, Ill.

KANSAS CITY.—*Honey.*—Demand poor, with a large supply of comb. We quote: Comb, 1-lb., fancy, 12@13; dark, 8@9. Extracted, white, 7; dark, 5@6. *Beeswax*, none on the market.

Mar. 21. HAMBLIN & BEARSS,
514 Walnut St., Kansas City, Mo.

DETROIT.—*Honey.*—Comb honey is dull and lower. It now sells at 11@12½ for white; dark grades almost unsalable. Extracted, 7@8; not much in sight. *Beeswax*, in fair demand, 26@27.

Mar. 21. M. H. HUNT,
Bell Branch, Mich.

SAINT LOUIS. *Honey.* Inquiries for strained were frequent, and business more satisfactory. No quotable change in values. *Beeswax*, prime, 27½.

Mar. 21. D. G. TUTT GRO. CO.,
St. Louis, Mo.

BOSTON.—*Honey.* We quote you our honey-market as being well supplied, fair demand. One-pound combs selling at 13@15; no 2-lbs. on hand. Extracted honey, 7@7½. *Beeswax*, none.

Mar. 26. BLAKE & RIPLEY,
Boston, Mass.

Thousand pounds choice, light-colored, extracted honey at 7c per lb. BYRON WALKER, Capac, Mich.

FOR SALE.—20 lbs. extracted clover honey, in new buckets, for $2. By the barrel cheap.
6-7d B. T. BALDWIN, Marion, Ind.

My 654 Colonies of Italians

Are wintering well, and, as usual, I will sell a limited number of them to reduce stock to the required number. Each hive shipped to my customers will contain a full prosperous colony of Italian bees, with a last year's tested queen, on eight Hoffman frames of brood and honey. As my main object in handling bees is honey, we raise all our queens in full colonies from cells built under the swarming impulse, using the choicest and most profitable stock to breed from.

Safe arrival guaranteed in May and first half of June. For terms please address

PUBLISHED BY A. I. ROOT
$1.00 PER YEAR MEDINA OHIO

Vol. XX. APRIL 1, 1892. No. 7.

STRAY STRAWS

FROM DR. C. C. MILLER.

KEEP SWEET, no matter how warm the discussion.

METAL COMBS again. This time they are invented in Germany.

EMMA SAYS that Doolittle's as near right as any, if he *is* all alone. Emma's a girl of pretty good judgment.

GOOD NATURE seems to be one of the prominent features that characterize the discussions of bee-keepers nowadays.

DO BEES SLEEP? The *Centrallblatt* thinks they have no need of sleep, at least not in summer. I wouldn't be a bee.

THE WINTER has not been very severe in Northern Illinois. Hasn't gone down as low as some winters by nearly 20°.

THE STANDARD FRAME of the British (14x8½ inches) has 119 square inches of surface; the French, 186; and the Simplicity, 161 square inches.

February was warm enough so I kept cellar door open day and night for a week. But the middle of March shows 8 to 12° above zero, morning after morning.

COST OF HONEY is hardly worth more discussion. So long as the matter is viewed from distinctly separate standpoints, there never can be any agreement.

I DIDN'T WANT the senior editor to get back north before danger of spring dwindling was over. Still, it seems good to have his signature *A. I. R.ed* throughout GLEANINGS.

"WE ARE RAPIDLY coming to the conclusion that bees need more ventilation in the cellar than many suppose."—*Foot-note on page 203.* All right, come on. I've been there for years.

Did the windmill spin faster
At sight of its master?
Did the cabbage forth shoot
When it saw A. I. Root?

A CORRESPONDENT of *B. B. J.* came near losing his life by means of an oil-stove without having the smoke carried off. No wonder those who have tried oil-stoves to heat winter repositories are down on artificial heat.

WINTER HEATING, which caused such a *heated* discussion in Germany, is settled down to the conclusion that, in the hands of Pastor Weygandt, it is a success, but he does not claim it as a thing for general use everywhere. For the majority, it is thought to cost more than it comes to. This doesn't refer to keeping cellars warm in winter.

"THE SWARMING FEVER is not present, we know, except as developed by external causes," says J. H. Larrabee, p. 194. No, we don't know—well, that is, what do you mean by external causes?

DON'T BE FOOLED by one or two warm days into bringing your bees out of the cellar too soon. Let 'em roar in the cellar if they want to. Just open all up at night and give them a good airing.

PHACELIA TANACETIFOLIA, the California honey-plant, according to two writers in *L'Apiculteur*, is not only a valuable honey-plant in France, but an excellent forage-plant. Bro. Larrabee, there's a field for experiment.

THAT TRIP up Wilson's Peak makes thrilling reading; but don't you think any man not in the best of repair who should undertake such a trip would be a good deal of a f—er—er don't you think he oughtn't to undertake so much?

IT DOES SEEM that we ought to come to some sort of agreement about grading before the subject is dropped. Some one may yet strike a lead that will help us out, and an hour or so in a convention will hardly settle it satisfactorily unless there is more previous discussion.

OLD BEES, according to Cantor Beck, in *Lpz. Bztg.*, winter as well as young ones. He united a lot of old bees and gave them a queen, and they lived as well as others, being the third colony, among 30, ready to swarm the next season. But wasn't this an unusual experience?

INCORPORATION, it seems, is not the thing objected to by the O. B. A. It's only that there wasn't more of it. R. McKnight says, in *C. B. J.*, "We never had any objection to our brethren across the border incorporating." But he thinks it ought to have been done by act of Congress.

THE CONGRESS OF PARIS agreed upon three frames as standard—a *high* frame 30x40 centimeters; a *low* frame 40x30, and a *square* frame 35x35. The *high* is for mountainous or cold regions; the *low* for hot, and the *square* for medium climates. The square frame is about 13¾ inches square.

LARRABEE proposes to start at the root of things by controlling fertilization in order to control qualities in bees. Control of fertilization seems hopeless; but its importance warrants much trial. But please, Bro. Larrabee, don't refer to N. W. McLain's experiments as any thing reliable.

THE BOARD of Lady Managers of the World's Fair have appointed ten ladies as a committee on "Bees and Bee Culture." They are Mesdames Olmstead, Doolittle, Howes, Cantrill, Shepard, Couzins, Hartpence, McCandless, Rue, Bartlett. Nice ladies, without doubt, and very properly behaved; but somehow I don't remember ever hearing of any one of them as a bee-keeper.

THAT CHEAP HARVEST DRINK, that I quoted from *C. B. J.*, J. A. Green feels so sure is all wrong that I'm afraid he is right. Hereafter, before I give a recipe for any drink I think I'll first drink a few quarts of it myself. I don't think the drink in question ought to be called "cheap," for you must swallow about a quarter of a pound of honey to get a pint of drink.

FAIR PLAY has been shown on the battlefield of the "cost" discussion; but Hon. R. L. Taylor, unwittingly no doubt, indulges in foul play when he accuses Doolittle of inconsistency in changing from 313 days at $1.25 to 81 days at $5.00. I think Doolittle had previously explained that, in one case, he charged for the whole year at a price that could be so earned, and in the other case merely for the days actually employed at expert wages. That's fair, isn't it?

WHAT OUGHT THE GOVERNMENT TO DO FOR APICULTURE?

VALUABLE SUGGESTIONS FROM P. H. ELWOOD.

Apiculture is a branch of agriculture, and as such is entitled to the same fostering care extended by the government to other branches of the same occupation. As a pursuit it is a new comer, an "infant industry," and we should therefore expect it to be treated with exceptional favor. Instead of this, however, the three hundred thousand bee-keepers of this country have been almost wholly neglected. There seems to have been enough money to spend on promoting the culture of silk, an article of luxury, but nothing for the production of honey, the most healthful sugar food in the world. Millions of dollars are freely offered for the production of cane sugar, an industry that needs the fatherly care of the government no more than does ours, if, indeed, it needs it as much. Bee culture is peculiarly important because it saves a product that, unless gathered by the honey-bee, goes to waste; also because of the offices the bee performs in the fertilization of the flowers of fruits, grains, seeds, etc. These indirect benefits are probably quite as important as the primary work of honey-gathering. As mentioned in my last, we have now under Secretary Rusk an effort by the government to protect us, for it has within the past year employed two able bee-keepers, Mr. Larrabee at the Michigan Agricultural College, and Mr. Frank Benton at Washington, to look after our interests.

This well-intended effort, however, is practically fruitless, since both of these men are under the direction of Chief Riley, of the Division of Entomology, who, no matter how distinguished as an entomologist, can not be expected to know much about practical and scientific bee-keeping, nor to be able to intelligently supervise the expenditure of money appropriated for experimental work in advanced bee culture. In proof of this assertion, notice the misdirection of the efforts of these two efficient men. Mr. Larrabee's time has been so fully occupied with the care and manual labor of the large Michigan College apiary as to leave him but very little time or energy for experimental work. Mr. Benton, I judge, has a desk in some dark corner of the Division of Entomology, and he has no bees nor other facilities for practical work. He has had enough light and time allowed him, however, to prepare a bulletin, to be sent to farmers and others making inquiries as to how they shall commence bee-keeping. Now, we do not need this kind of work at all, for we have plenty of handbooks and journals devoted to A B C instruction. What we need is advanced work—work that private individuals can not perform because of expense, or lack of time or facilities for doing it. We do not care to have the government make any efforts to increase the number of bee-keepers until after it shall have made successful efforts to enlarge the markets for their products. We hardly think that, in the fostering care the government extended to the cotton, iron, and other manufacturers, it ever became necessary to issue bulletins describing the best course for beginners to pursue in engaging in these occupations. The government can and should help us by making original investigation on the uses of honey in the arts and manufactures, and by collecting and disseminating information already known to the few, on these points; also by investigations as to the healthfulness of honey, by comparing its digestibility with that of cane-sugar syrup and other sugar and heat producing foods. The various diseases of bees, particularly the pest of foul brood, should be investigated, and methods of treatment disseminated. The Canadian government has a foul-brood inspector, and also grants pecuniary aid to its national society for their efforts in promoting advanced bee culture. Some parts of our country are said to be as badly afflicted with this contagious disease as is Canada; but we get no help, although it is expected that the Bureau of Animal Industry, a division of the Department of Agriculture, in charge of the diseases of domestic animals, etc., will call for an appropriation of one million dollars from the present congress.

The important part the honey-bee performs in the fertilization of flowers should be so fully investigated as to make the results authoritative, and the report spread broadcast among farmers and fruit-growers. Bee-keepers now suffer serious loss from the prejudices of these classes who should be our strongest friends and supporters.

A number of disputed as well as a number of undiscovered functions in the physiology of the honey-bee should be definitely established. It may be said that these do not concern the ordinary bee-keeper. Not so; for I have recently had occasion in practical bee-keeping to refer to several of the most obscure. An experiment apiary, conducted by so practical and skillful a bee-keeper as Frank Benton, ought also to establish many useful points in practical bee-keeping. The different races of bees could be tested, and trustworthy reports made as to their merits, without compelling a multitude of bee-keepers to invest of their hard earnings in making what are usually very imperfect tests. The trial of the so-called Punic bee by the bee-keepers of this country will probably cost thousands of dollars. Mr. Benton, with a few swarms of bees at his command, quite likely could have decided on their worthlessness at an expense of less than twenty-five dollars.

A statement has recently gone forth from one of our most distinguished State entomologists, Dr. Lintner, that it would be desirable for the destruction of certain insects that fruit-trees be sprayed with arsenical mixtures while still in bloom, and that he refrained from advising spraying at this time only because of the assertion of bee-keepers that it poisoned their bees. The proof of this poisoning, while conclusive with bee-keepers, was not wholly so with Dr. Lintner (it is feared it will not be with fruit-growers), and he asked that conclusive experiments be made during the coming spring. As the danger is imminent, and concerns the bee-keepers of many States, it would seem very appropriate that these experiments be conducted at Washington, and the results put into the hands of fruit-growers, so that, if we find it necessary to go into court, we may have proof that these untimely sprayers had knowledge of the crime they were committing.

It is not my purpose to discuss the merits of our system of governmental assistance; but it seems to me that, since other industries are reared and fattened at the government crib at our expense, we might now receive back a small percentage of the taxes levied on us for the maintenance of our older and stouter brothers. Apiculture is now a section in the Division of Entomology; so at one time was ornithology; so was silk-raising. Both have been raised to independent divisions. I leave it to any intelligent man whether our pursuit is not of more importance than either or both of these divisions. I should be glad to fortify my position with statistics, but, unfortunately, we have none. The census enumerator informed me that he had no place on his blanks for honey. The least that we can ask is, that the section of apiculture be raised to an independent division, and that it be put under the supervision of some practical bee-keeper like Benton, of sufficient scientific and executive ability to perform the duties of the office. I want to emphasize the fact that we shall have nothing satisfactorily done until the work is in charge of a bee-keeper. To ask an entomologist to superintend this work is like putting a lawyer in charge of a hospital, with a corps of physicians doing his bidding. A first-class experiment apiary should be established at Washington. Larrabee, or some other good man, should be called in as an assistant; and a chemist, botanist, and other help should be at the service of the superintendent at all times. Bulletins should be issued to bee-keepers, giving results of work done, and also giving crop reports, gathered with a thoroughness and exactness impossible with the private enterprise now collecting them. Lastly, congress should remember the blow they dealt us when they removed the duty on cane sugar, the chief competitor of honey, and provide liberal means for carrying on this apicultural experiment station in the most thorough manner possible.

The State of New York expends about $12,000 yearly on farmers' institutes; $40,000 on experiment stations, and $92,000 on the dairy commission. Bee-keepers help pay for all this, but get no benefit. In justice the State ought to appropriate at least a thousand dollars to be expended under the direction of practical bee-keepers in holding one or more bee-keepers' institutes or conventions, and for other necessary work in advanced bee culture. Other States should do likewise. Illinois has already set the example. Our country is so large that it is difficult to maintain a national organization. With State aid this could be made a delegated body, with the traveling expenses of delegates paid. P. H. ELWOOD.

Starkville, N. Y.

[Mr. Elwood has so thoroughly and ably covered the subject above, that we have but little to add. We heartily indorse what he says, and hope the article will be widely copied, not only in the bee-journals, but in the agricultural papers also. Silk culture, in point of magnitude and importance, is small in comparison with that of bee culture. But perhaps the only reason why we have not risen to greater recognition at the hands of the government is because bee-keepers have not taken the pains to properly present their needs. Let's see, Mr. Elwood, Mr. Hersheiser, and Capt. J. E. Hetherington were appointed by the N. A. B. K. A. at the meeting in Albany to look after these matters. We are glad that they are already at work. GLEANINGS will gladly assist in any way she can.]

THE VALUE OF DRAWN-OUT COMBS; WHEN AND HOW TO SECURE THEM.

A MOST VALUABLE ARTICLE ON THE APIARIST'S BEST CAPITAL; BY C. A. HATCH.

The best thing a bee-keeper can have in the spring, is plenty of hives full of bees; and the next best thing is plenty of good combs to go with them. The difference between 20 good colonies in as many empty hives (no combs), and 10 good colonies in 10 hives full of drawn-out combs, is not so much as some might think; how much do *you* think? Every bee-book has its chapter on increase of colonies; but how many have a chapter on increase of combs? Yet we can but give it second place in importance to the bee-master. True, if you have bees enough, in time you will get the combs; but to get them at the least expense of bee-force, which is our capital stock, and in the shortest time, is the object of this article. If we lose the use of our bees in honey-gathering because all their force is used up in comb-making, we have lost the use of our capital for that season; and, if a hard winter follow, it may be for the next year too; so time becomes an important consideration. I remember one year in which, during basswood bloom, good colonies filled an extracting-super in two days chock full, and yet the flow continued. Having only one set of combs for each colony, the bees were forced to spend almost time enough to fill another set of combs before the honey already gathered would do to extract. In this instance, one set of combs was almost as good as a colony of bees. This was an unusual year, but I have found that a surplus of empty combs in the spring is a grand thing to have, if we do not get them by the bees dying to make a surplus.

How many combs are profitable? After careful thought and observation I have fixed on three extra hives full for each colony, spring count, as just about the right number. These, with what foundation can be used advantageously during the season, ought, with good management, to insure every bee opportunity to do its very best, and not hang out around the entrance as a sign there is no room within.

HOW TO USE THEM.

At the risk of getting the cart before the horse, and telling how to use the combs before the way of getting them has been told, we will say right here that one set of combs is to be used for increase and two for surplus storage; not that we mean that each swarm is to be hived on a full set of combs, but one set is to be judiciously used for the benefit of the swarms or increase of bees; but to tell just how these are used would require an explanation of my entire method of increase of colonies, and would make this article too long.

The other two sets of combs are to be used as extracting supers for the strongest colonies on the tiering-up plan.

COMB FOUNDATION.

I regard comb foundation as an advance in bee culture second only to the movable-frame hive in importance, and it is to this we must look mainly for our new combs. But to get the most advantage from it, care and judicious management are required. I have seen instances where foundation had been used so as to be almost if not quite a damage to the bees. But I have noticed that the ones who used most foundation are, as a rule, the successful ones.

HOW TO USE IT.

In full sheets, always. If you have but ten sheets it is better to put nine in frames so as to fill them, and cut the other sheet into half-inch starters for the rest of your frames, than to divide the lot into quarter or half sheets. If this be done you are sure to get perfect combs as far as the foundation goes; and, remember, a comb once finished is good for all time so far as we are concerned. They are the foundation of your business, part of your capital stock, and let them be just as perfect as you can get. If the foundation is cut into strips to quarter or half fill the frames, the chances are, that, as soon as the bees get below the starter, drone comb will be built, and this is just what you want to avoid as much as possible; for I have noticed that, be just as careful as we can, and keep out all drone combs as a whole, there is sure to be enough in the hive. Either by the mice gnawing the combs, holes left from cutting out queen-cells, or some way, it gets there.

TWO WAYS ONLY TO GET COMBS.

1. Having the bees build them; 2. Using foundation and having them drawn out.

The difficulty with the first is in getting too many imperfect combs, either crooked or too much drone comb, and it is too slow. I fully believe that, up to a certain amount, say five or six combs, bees in a reasonably strong colony will make them entire with as little loss of force as in any other way. I believe with Dr. Miller, that a certain amount of wax is secreted any way, whether we save it or not; and if I were sure of always having vigorous young queens in *all* my swarms I would hive them all on empty frames only, for I am sure we lose bee force right there; but the loss is more than offset on the other hand by the imperfect combs and the annoyance of righting them. So, practically, we are reduced to the method of increase of combs; i. e., foundation.

WHEN TO PUT IN FOUNDATION.

Not too early in the season, usually not before swarming commences. A certain amount of heat, at least 100°, I think, is necessary to make the wax soft enough for bees to work out into combs; and up to June 1st to 10th the temperature of the hive is not high enough for wax-working—first, on account of the weather outside; and, second, on account of lack of numbers in the hive to maintain the required heat. Another reason why it must not be put into the hive too early is, that bees will not work on it but to a very limited extent before honey is coming in. True, some years we get honey from fruit-bloom and dandelions so as to give the bees quite a start; but this would better be used to fill the combs you already have with brood, to push things later on when clover is in bloom.

HOW MUCH AT ONCE.

Do not make the mistake of putting too much foundation in a colony at once. I went to see a bee-keeper last summer, and found plenty of his strongest colonies with eight full frames of foundation over them, while other colonies not quite as strong had none, and were really suffering for lack of room. What was his duty in this case? First, take out four frames of comb from the colonies having no foundation, giving these to the colony having eight frames of foundation, and giving the four frames of foundation (displaced) to the one losing the frames of comb, then all will be merrily at work, not having so big a job as to become discouraged; and the result is, eight frames of comb in less than half the time he would have had them if all left in one place, and he has saved all this time for the bees, which means more honey, and therefore more money. As a rule, not over two frames should be given to a colony at once, and not that if there are not bees enough to cover them entirely.

WHERE TO PUT IT.

Moderately strong colonies seem to draw out and finish up combs better than very weak or very strong ones; therefore of ten given colonies, if five were medium and five strong, I would take combs from the medium, substituting foundation and giving the combs to the strong, with, say, one frame each of foundation, for I have found that a colony strong in bees will draw out one or two frames of foundation at each time of extracting, at little if any loss of honey; and before I got all the combs I wanted, I made it a rule to give them at least one frame. Weak colonies should be made to draw out combs for the use of the strong ones. The few bees they have are compelled to remain at home to care for the brood, and maintain the heat of the hive, so they can be kept busy working for their more prosperous brethren, or perhaps *sisters* would be more appropriate. Always put foundation between frames of comb if possible, and near the center of the hive, if the colony will bear to be spread that much.

FALL HONEY AND COMBS.

The honey we usually get after basswood is dark, and brings but a small price in market; hence, this is one of the best times to crowd the bees in drawing out and finishing up combs, to be ready for the white honey the next year. If you can so manage that you have turned *all* this dark honey into wax, you have done well and increased your capital at the smallest possible expense. But here is a point of advantage few bee-keepers have taken, for a sale of foundation in August or September is very rare, and yet I have found it one of the best times to ge combs.

In closing I should like to emphasize three points mentioned as seeming to be of greatest importance of any: 1. Full sheets always; 2. Not putting too much in a hive at once; 3. Turning buckwheat or late honey into combs.

Ithaca, Wis., Mar. 3. C. A. Hatch.

[Mr. H.'s remarks smack strongly of experience; and so many things in it corroborate some of our own experiments during the past summer that we feel like putting the whole article in Italics. It should be borne in mind, that Mr. Hatch's hints have a special reference to the producer of extracted honey; and to such a one, drawn-out empty combs are his best stock in trade. Some of these things we have known of before; but it is necessary to have good things pounded again and again into our heads until we condescend to try them.]

PRODUCING EXTRACTED HONEY.

REQUISITES FOR; COST PER POUND OF EXTRACTED HONEY.

I am asked to answer the following questions: "What are the requisites for producing extracted honey?" "What kind of packages do you use in shipping and retailing the same?" "How do you dispose of the most of your honey crop?"

Now, friends, I don't know that I can handle this first question to suit all places. It covers a great deal of territory. Locations will vary somewhat, but the first and most important requisite is an abundance of honey-producing flowers from early spring until late in the fall. Here in the North, if I could have it to suit me, I should want to locate where there were large quantities of fruit-blossoms—apples, peaches, pears, plums, etc.—followed by red raspberries, gooseberries, and other small fruits, and these succeeded by dandelions and plenty of white clover and basswood. Then should follow plenty of fall flowers—buckwheat, goldenrod, heart's ease, smartweed, asters, etc. If we can not have all of these good flowers in plenty, get as many as possible. Of course, in the South the honey-bearing flowers will be different. Every country has its own flowers. But honey-flowers we must have, or we shall get no honey. The more flowers there are, the better.

The next important item is plenty of bees to gather the honey. What kind of bees is best? Now, to tell the truth, I don't know. I commenced with the blacks, and I must say they are hard to beat. I have tried several strains of Italians, some of which have done pretty fair work. But I think the hybrids are better workers than the pure Italians. I am now trying the Carniolans — the dark-colored ones. They have done first-rate for me the last two years. In fact, they have done the best of any bees that I have. My home yard of 100 colonies consists of Carniolans.

Now, after we have got in the right location, and have the bees, we must have an apiarist that knows how to handle the business; and, in my opinion, to secure the best results, the apiarist should own the bees; or, in other words, the owner should know all about the business. He or she may hire the most of the work done by others, but the owner should oversee every thing. Very much depends upon very small details. Every thing that is to be used when the honey-flow comes should be provided before the time it will be wanted. Have every thing ready—hives, extractors, and all other tools; also packages for the honey crop, and a place to store the honey. We have our packages now on hand to hold our next crop. We may not get a crop, but we must be ready. If we don't use the barrels this year, we may next. See to it that the bees are in first-class condition in the fall. Plenty of honey means good strong colonies in spring. A man, to be successful with bees, must have a liking for the work, so much so that he will pick up every thing on the bee business, and read it. Not that he is expected to follow all that he reads, but he may get a good deal from another's mistakes. I doubt whether any of us knows all there is to be learned about the business, so we must study and think, and act according to our best judgment. If we have more bees than we can work alone, hire help. We hire young men and boys. A boy twelve to fifteen years old can do first-rate work extracting honey, if he has some experienced hand to tell him just what to do. One good hand that has worked with the bees two years can take charge of two green boys and get good results from their labor. Our extracting season lasts about four to six weeks. We give a green boy twelve to fifteen years old $8.00 a month the first year. If he proves to be a good hand, next year we give him about $2.00 more per month. If he stays with us, we keep raising his wages up to $20.00.

Another important item in producing extracted honey is to have plenty of extra empty combs, so when the honey-flow comes we can tier up and give the bees plenty of room to store honey. We work our L. hives three stories high during the honey season. In the fall we take off one set and store them away until wanted the next year. In this latitude I take them off in October, and pack them away in the third stories, piled one on the other in our comb-room. If they were taken away from the bees much sooner than October, the moths would destroy them, unless we smoked them with sulphur. Combs packed away in a tight room where they will freeze hard are safe from the moths. I have kept them all summer with no signs of worms about them.

For shipping extracted honey we use oak barrels, iron-hooped, holding from 360 to 600 lbs. For our last crop we used some molasses-barrels made in the South. In these we put our dark honey, and sold it to the bakers. Our nice white honey we sell to dealers for table use. We also sell several thousand pounds at home, to farmers and city folks. We keep three stores in our town supplied with honey, put up in tin pails of different sizes—pint, quart, two, three, and four quart. We get the pails of A. I. Root.

COST OF PRODUCING EXTRACTED HONEY.

You ask me to give you the cost of producing extracted honey, and refer me to Messrs. Taylor's and Doolittle's articles on the cost of comb honey. I have records of the amounts of honey that we got for a long time, and how many bees we had each year; but what the crop cost per pound I can not even make a good guess on. In 1890 our honey cost us a dollar a pound; in 1891 we got 30,000 lbs., and sold at 5, 6, 7, and some at 8 cts. The crop gave us a living for the year, and about five hundred dollars over. What it cost a pound, I don't know; but I am sure it did not cost as much as we sold it for. The way we are fixed I can not get at the cost exactly. We have 20 acres of land to work, and often we get through with the bees, and get home before night; then we set all of our honey-boys at work on the place, hoeing and cultivating, killing weeds, etc. I think it would be very doubtful whether any one could tell just what a crop of honey costs. I am sure that no one can make a statement that would do for every year on the same location; then, again, locations differ much, and management would make a large difference. There is as much difference in bee-keepers as there is in other folks. If I write an article on any subject I want at least to satisfy myself that what I have to say is practical. Mr. Doolittle tries to make the cost of comb honey as big as he can. When he charges up $5.00 a day for his time, going to conventions, price of bee-papers, and time of reading the same, etc., why does he charge it all to the production of comb honey? If I am not mistaken, his queen-traffic brings him more money than his honey. Why doesn't he divide some of those expenses with his queen-trade? It is all guesswork. He doesn't know, I don't know, and who does?

Platteville, Wis., March 7.

EXTRACTED HONEY.

WHAT INJURES ITS SALES; SHIFTLESSNESS OF BEE-KEEPERS, ETC.

On page 121 for Feb. 15, Mr. Geo. F. Robbins relates the observations and experience of his grocer who deals in honey. The grocer said that there would be nothing in offering premiums at fairs for honey extracted on the ground, seeing honey-extractors in operation, and that the way in which liquid honey was obtained would do nothing to remove the generally prevailing opinion that extracted honey is manufactured or adulterated. This is far from a reasonable conclusion to warrant belief. To see and to understand is to believe. All manner of people are convinced in this way. Within two miles of our place there is a city of 16,000 people; and as there is a pretty driveway from the city through our place, many people stop with "the man who keeps the fire-bugs," for honey. We always show these city folks the extractor, explaining how used; and if there is honey to extract, some is thrown out, that they may see the *how*. Some remark, "We have often heard of this way of taking honey, but had little or no faith in the story; but one must believe when he sees." These people become our best customers.

When the grocer stated to Mr. R. that "the only way to get the confidence of the people is to produce and put on the market honey of first-class quality," he was preaching logical doctrine. Here the man displays knowledge gained by experience. He is not the only person who has learned this lesson. The wise profit by this experience; but foolish, short-sighted men go on from year to year producing and putting on the market honey of an inferior quality, made so by lack of experience, want of judgment, or thoughtlessness. At one time the honey is extracted while thin, only in the condition of rank-flavored nectar, and often, in this state, no effort to place it where it might be improved by evaporation. Again, it is stored in shaded or damp rooms where both comb and extracted honey rapidly deteriorate. Who has not seen beautiful white combs gradually taking on that watery, unsightly—yes, sickly appearance? Honey left to the care of the bees never gets so, unless the hives are located in a damp, shaded place.

Extracted honey that is thin from any cause should never be stored in any other than shallow, open-mouthed vessels, then kept in a warm, dry, well-ventilated place; and the same theory holds good with comb honey.

No doubt the majority of bee-keepers take great pains to excel in the matter of producing and placing on the market honey of a first-class quality; but it is a fact, deplorable and injurious as it is, that many who are engaged in producing honey are careless and indifferent as to the quality of their product. The injury this class are doing to the industry is very great. It may sound harsh, but I must say they are a nuisance to the fraternity.

As we buy from producers and dealers in honey each season not less than 100,000 lbs. for our retail trade, we get some sorry experience. I'll give a sample or two. A party wrote us last fall that he could ship us 20 barrels of pure orange-bloom honey, mailing at the time a sample of it. When received, four barrels of the lot was about all palmetto honey, dark and ill flavored. Again, samples of mesquite honey of best quality were sent; and to this party an order was given; but a few cans of this lot was alfalfa, of the meanest kind. Other orders were sent to the same parties, but more and more alfalfa was put in each lot, the last being entirely alfalfa, dark and strong in flavor, and by no means "fit to set before a king."

Another lot received from a producer had been extracted in the nectar state, and then stored in cans reeking with the fumes of kerosene oil. This stuff may do to feed bees, but not to sell for table use, if a regard for one's reputation is thought of.

It is surprising how many there are who, for the sake of a little temporary gain, violate with impunity the principles of honor and fairness, forgetting that their betrayal of trust must eventually fall upon their own heads with crushing weight.

ADULTERATED HONEY.

As we sell honey in every town and city within quite a distance of us, we see much of the honey-markets. Within the last two years many city packing-houses have gone into the business of putting honey in tumblers and bottles. Some of this we find to be good pure honey; but for the most part it is a glucose mixture surrounding a small piece of comb honey. Does this honey, or stuff, detract any from our sales of choice honey? We think not; in fact, we are of the opinion that we sell more honey because of this adulterated stuff.

We call on a family to see whether they will buy honey. The question is asked, "Is it the strained honey?" Answering, we say, "Yes, we have either liquid or comb."

"Well," they say, "we don't want strained honey. We got some of it at the store, and that's a fraud."

Now, we give them a sample vial of just what we will bring them. Then to see them lift the frown, and say, "Oh! that's different; that *is* bee honey. If you bring us that kind you can depend on us for good customers."

Our reply is, "Yes; if, when delivered, you do not find it equally fine as the sample, you need not give us your money."

In this way we add another to our list of thousands of permanent customers who will buy no honey put up by packing-houses.

But, Mr. Editor, I would not discourage your efforts to bring to justice these robbers who are engaged in the nefarious scheme of bottling glucose with the lie "Pure Honey" pasted on the packages. J. A. Buchanan.

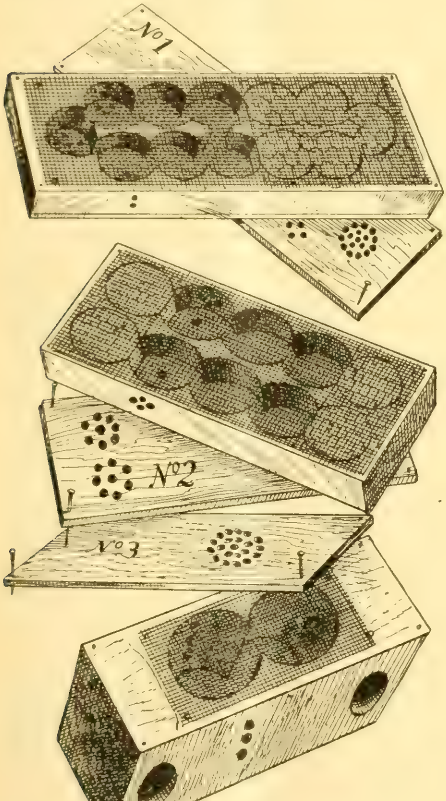
Holliday's Cove, W. Va., March 8.

QUEENS BY MAIL TO AUSTRALIA, 11,500 MILES AWAY.

CAGES.

In my last article I said that, according to my opinion, the size of the cage (5x2x1½) as given in the Postal Guide should not be specially considered when sending queens to Australia, as there was no law governing the matter regarding queen-bees to that place, other than having the packages they were sent in conform to what would be allowed in our domestic mails. Why I looked this matter up so closely was, that I am not just pleased with the "Root-Benton" cage, for the reason that the candy-hole is liable to become clogged with dead bees, which reason the editor speaks of on page 72 of Gleanings for 1891. Should this cage happen to so go on board of the steamer that the candy end is downward (which would be its tendency every time, that end of the cage being much the heavier), the result would be, that, should there happen to be any dead bees in the cage, they would fall down into the candy-hole, thus virtually cutting the bees off from their food, causing them to starve. I have evidence that this was the cause of the death of some that I sent, as those reporting to me speak of two of these cages as coming with "every bee dead, all bright and clean, with little of the candy eaten, and many bees wedged into the candy apartment."

This difficulty confronted me when sending to New Zealand in 1884, so I fixed the cages then used (2x2x5½) with a large candy-hole in either end, and the apartment for the bees in the middle. This gave the bees a chance to feed from either end of the cage. This old cage was all right on this score, but, to my notion, it confined the bees too much in a heap during the extreme heat they must endure in passing through the torrid zone; so in shipping this year I tried to overcome this difficulty. Accordingly a part of the queens were sent in the Root-Benton cage, a part in a cage 5¼x2¾x⅞, having ten holes bored in the same, with partitions throughout, so the bees could spread out all over the cage, except that part filled with candy; or, when cold, cluster up as compact as they please. Another part were sent in cages 7¼x3x½, having twelve holes in them, with partitions arranged as in the other; but with this one the candy was all put in one end, five of the holes being used for the same. This gave the bees seven holes to spread out in on the start, and more room as the candy was eaten. This cage was also provided with more thorough ventilation than any of the others, good ventilation being provided in two of the seven holes, to the amount used as a whole in the Root-Benton cage, while the extreme end hole was bored clear through, wire cloth being put on either side of it, so that the bees could come out in this part of the cage, and, by fanning their wings, cause a circulation of air throughout the whole cage, similar to the way they ventilate their hives from the entrance.



DOOLITTLE'S FOREIGN MAILING-CAGES.

I have been more particular in describing this latter cage, as all the cages of this description sent proved a success, the bees and queens arriving in fine condition in Australia after a voyage of 11,500 miles, and a confinement of from 37 to 40 days. The candy used in all of the cages was the Good candy. The candy-holes in all were coated with paraffine by pouring the same in them, when at a very high temperature. I like this better than putting on with a brush, for in this way the paraffine is forced into the wood to the depth of one-sixteenth of an inch or more, so there is no chance for the moisture in the candy to escape. Over the candy I placed a piece of thin comb foundation, pressing it into the wood all around, so that this candy apartment would hold water like a pail. Nine of the fifteen queens were sent to S. A. Bradley, Denham Court, New South Wales; three to Jas. McFarlane, Lyndhurst, Victoria; two to A. Walker, Redland Bay, Queensland, and one to R. J. Cribb, Brisbane, Queensland. Both of those to Mr. W. went alive, and were in flat cages. Mr. W. says that, of four others received from the United States, all were dead except four workers in one cage. The one to Mr. Cribb was in a flat cage, and that went through in fine condition. Of the three sent to Mr. McFarlane, two were in the Root-Benton cages and one in the flat cage. The one in the flat cage went alive, the two in the Root-Benton both dead. Of the nine sent to Mr. Bradley, three were in the Root-Benton cage and six in the flat cages. Of these, one in the Root-Benton cage went alive and four in the flat cages. Six of the fifteen queens went on the October steamer, four out of the six arriving dead; while of the nine sent on the August and September steamers, seven went alive. Mr. McF. writes that those sent him were evidently suffocated, and must have been in a closer mail-bag or in a hotter part of the ship than those sent him by Mr. Root, according to their appearance; while Mr. B. says, in speaking of my last shipment to him, "A circus and menagerie came in the same vessel with the queens, and all mail matter was crowded into all sorts of out-of-the-way places, which did not give the queens the usual chance of living." Understanding this state of affairs, it is a little suggestive that the four in the Root-Benton cages all died, while the two in the flat cages went alive. As Mr. Bradley seems to be a close observer, I think some remarks of his on the different cages will be of interest. Speaking of the half-inch cage he says: "This cage seems to come as near perfection as possible, the bees and queens in the same being as lively as if they had been confined only a few days." Of the seven-eighths cage he says: "It is very good, but would be better, I think, if the air-holes were a little larger, so as to allow freer ventilation." Of the Root-Benton cage he says: "The objections to this cage are, first, in having only one means of access to the stores. In one of these cages the queen was dead in the food compartment, and the hole behind her was blocked with bees. Second, owing to its block form it packs too well, or too closely with other articles. If the sides were fluted, and air-holes punched in the flutings it would be better."

WIRE CLOTH.

Mr. B. further says: "I should like to call your attention to the *green* wire cloth used on some of the cages. The queen and bees in these cages were literally covered with a fine green dust, and it was not until several days after introduction that the queens were cleaned from it—in one case, not for two weeks; and in trying to get it off from the queen, the bees removed every particle of "fuzz" from her back and shoulders, leaving her as shiny as glass. Those with the black wire cloth were perfectly clean."

PROOF OF VALUE.

When I started these queens for Australia I had some misgivings about their being of any value to those who purchased them, fearing their long journey, confinement, and the necessary abuse to which they must be subjected, would injure them. But it would seem that these misgivings were groundless, in part at least, for Mr. Walker writes that the two sent him "showed no half work and half play, or half brood and half honey in one comb, for they proceeded to fill up the combs to their very corners, and top-bars with brood." Mr. Bradley says nothing as to the laying qualities of those received; but it would seem that he went right to breeding from them, and gives the point which I consider of *greater value* than the prolificness of the individual queens, which have been subjected to such great abuse as they must be in going so far, and the *one point* above all others which is to the interest of all apiarists. He says, in speaking, of the young queens: "Their queen-daughters are very even layers, and very prolific. They fill the brood-frames from side to side and from top to bottom, and their worker progeny leave nothing to be desired in the way of work. On the whole we are more than satisfied with the result of our enterprise." This proves the position I have taken in the past, that, through a direct cross, comes the greatest energy and activity in our pets.

Borodino, N. Y., Mar. 5. G. M. Doolittle.

[We are glad that our friend Mr. Doolittle has taken hold of this matter in the careful, painstaking way so characteristic of his methods of work. There is no doubt, in point of theory and fact, that his flat cages are better than the block cages we used with such good results last season. The latter has done marvelously well; but where there was an opportunity for comparison it was evident that the flat cage was the better. We have examined all the cages carefully; and while our correspondent seems to favor style No. 1, we rather incline toward No. 2, as shown in the engraving, because it is stronger and of better proportion. This latter has the very desirable feature of having candy at *both* ends; and, besides, it seems to us that it can be made equal in point of ventilation to the still flatter cage No. 1. This, as nearly as we can remember, before we submitted it to our engravers for reproduction, seemed to be frail, and not one we would dare to trust to the vicissitudes of a long journey. The reason we decided on the block form in the first place was, because the postal regulations stipulated that kind of cage; but if the "powers that be" will permit these flat cages to pass through the mails (and they did in Mr. Doolittle's case) they (No. 1 or 2) will be the ones to adopt.]

COBS AND KERNELS.

INTERESTING FACTS AND OBSERVATIONS BY F. GREINER.

1. From the standpoint of the comb-honey producer I have never found it profitable to practice dequeening for the purpose of increasing the honey crop, except in connection with the renewal of the queen; and in that case I should rather consider it a remedy for curing or preventing the swarming fever. It requires very good judgment in anticipating the honey season, in having the young queens commence laying just at the right time, etc. One may easily fail.

2. It seems to be the desire of all colonies of bees in normal condition to breed many drones at a certain time of the year. Gratify this desire, and a state of contentedness and general harmony is established, without which no colony may be expected to do its utmost. Now, while some of our noted bee-keepers, Baron von Berlepsch at the head, have theorized that drone comb is out of its place in the brood-chamber, many of us have noticed colonies almost overrunning with drones, outstripping others that were practically without them; and I believe it best to allow each colony a liberal amount of drone comb; perhaps half an L. frame full may not be too much.

3. I believe the majority of our comb-honey producers, and also the manufacturers of comb foundation, are in favor of using light foundation (full sheets) in sections, and it may be poor policy to oppose its use; but should we not in the first place consider the wishes of the consumer? To judge others by myself, I should say they do not want it. I do not like to chew the disagreeable backbone, for even the lightest brand is not entirely worked out. May we not injure the honey-trade by the use of foundation in sections except for starters?

4. It is not so much the good quality of the section as it is the quality of the honey, the color, finish, texture, and flavor of the honey the section is filled with, that pleases the consumer most.

5. They seem to be periodical, these discussions of "Italians versus Blacks." From time to time they have made an appearance, and also again of late. I have always been greatly in favor of the black bees, particularly because their product is so much better as to looks, and sometimes I have been quite uncharitable toward those booming the yellow race. Well, now, after an experience of over 15 years with both races I am still undecided in the matter. I think that, if the management requires to hunt out queens often, then the pure Italian bee takes the preference.

6. To find a black queen in a powerful colony is not often an easy task. Many times every comb has to come out of the hive; the remaining bees must be examined critically, perhaps dumped out into a sheet; and I am not sure but that sifting the entire drove through a sieve of queen-excluding metal may yet prove the quickest way to attain the desired result.

7. My colonies of pure Italian bloods do more propolizing than either hybrids, blacks, or Carniolans. They store a greater amount of pollen, also more honey in the brood-chamber.

8. On page 155 Mr. Elwood expresses almost exactly my ideas of grading comb honey. Undoubtedly he is right in saying, "Unsealed, partly filled sections, and such containing bee-bread,* should be kept at home." Some years we have a good many sections which, although all built out and sealed, are yet light in weight; the combs are not full thickness. No objection could be raised to shipping such; but they would better be crated by themselves, as it is desirable to have all sections contained in a crate as near alike in weight as is possible.

9. The Porter escape is perhaps ahead for use *on the hives;* but on a whole stack of supers the four-point Dibbern escape gives better satisfaction. The light falling in through the center hole attracts the bees, and causes them to come out much quicker. Robbers will seldom obstruct the passage at the points, but will hover on the screen just above the center hole. I used to think that the most natural escape, the one which would facilitate the exit of the bees most, was the old Reese cone-escape. In this, however, I was mistaken; for, after a while, the returning and the robber bees, also young bees from within, begin to cluster at the apex of the cone, and hinder the escape of the bees.

10. Removing the full super from hives in out-apiaries—many times, I practice the old method of driving bees down with smoke, lifting up the super quickly, brushing off what bees are on the bottom, then stacking up from 10 to 12 supers on top of an escape-board, also placing one on the top of the stack, and await

---

*In all my experience I have come across but one person fond of bee-bread, who actually preferred honey containing a liberal amount of it.

results. For this purpose no escape seems to work any better than a combination of the four-point Dibbern and the later Reese (such as I mail you to-day). To still more facilitate the work, I provide a case near the center part of the stack with a ⅜ hole at each side, placing a wire-cloth cone over each. It will not be long before every bee will have left the supers.

11. Many of us have been successful in wintering in chaff hives by giving upward ventilation through a thick chaff cushion; and it seems to me we ought to go very slow in changing our method. The objection of cushions getting wet and cold does not hold true so far as I have observed. Only the upper part of the cushion gathers moisture and becomes wet; all the rest remains dry and warm. By raising or removing the roof on a fair day, this condensed moisture can easily be made to disappear. When upward ventilation is given I think it is best to close up the entrance to within two inches; when not, giving full entrance is perhaps the better. A board stood up leaning against the hive in front of entrance, to break the force of the wind, also to shield against the rays of the sun, is of advantage.

12. I wish to speak of a bee-cellar with a *cemented floor*, which a friend of mine in this vicinity uses with good success. Two weeks ago the 150 colonies therein were in fine shape, apparently, only a few dead bees being on the floor. A few years ago this same cellar had 10 or 12 inches of water in it nearly all winter; still the bees came out all right in the spring.

13. If a colony of bees arrives at its maximum strength any length of time before the honey-flow commences, it will not do nearly as well as some other colony just getting there as the season begins. This is particularly the case with such as have older queens.

14. Machines for folding sections will not be the desideratum with me until, by a happy combination with the foundation-fastener, the starters can be also fastened in by the same operation. If I can not save time, nor do the work better by using a machine, why use it?

15. Dr. Miller says, in Feb. 1st GLEANINGS: "But is it true, that bees do not become field-workers till 16 days old? I have seen bees 5 days old carrying pollen." Then Dr. M. does not accept the sixteen-day theory, does he? I am pretty sure that, under normal conditions, bees do not become field-workers until 16 days old. What they may do under other conditions I have not observed. The A B C tells us, "Bees become field-workers when two weeks old, sometimes when but one." Prof. Cook is undecided; he gives the age as two weeks, but thinks that, under abnormal conditions, they *may* go into the fields when one week old. James Heddon teaches, "Bees become active workers in gathering honey when from 4 to 8 days old." According to G. M. D., this is not the case until they are 16 days old. Why so much indecision and differences in opinion, when the facts may easily be ascertained? A few experiments thoroughly carried on would tell the story.

Vogel conducted an experiment of this kind some 15 years ago. He arrived at the same conclusion G. M. D. did. The experiment of Vogel is so far all the more interesting, as he formed his experimental colony by the use of brood-combs containing only sealed and hatching brood, so no old bees could possibly be in the hive. By the experiment, Vogel learned in the first place that bees need no education or training to perform the functions which are performed inside of a hive of bees. The faculty is born in them for nursing the brood, building comb, etc. Further, he observed that no bee left the hive for any purpose until the sixth day from the time of the first bee emerging from the cell. On that day, in the afternoon, a few came out for a playspell; after this the hive became perfectly quiet. The next day in the afternoon, more bees came out for a playspell, and so on, more and more every consecutive day, but always becoming quiet after the playspell; not a bee went foraging until the sixteenth day in the afternoon, after the usual playspell, then just a few bees were seen to return with their pollen-baskets loaded. From this time on, the colony became more and more active. Some time during the course of the experiment the colony was deprived of its combs and provision; still, not one bee would go out in search of food, although the day was fair, and nature furnished both pollen and honey. The bees were nearly exhausted when their provisioned combs were returned to them, and they were thus saved from starvation.

Since Vogel is one of the best authorities of the present day, I have no reason to doubt his statements; still, there may be others who have not the faith in him, considering what other authorities claim, and I would suggest that a number of our ablest men conduct such experiments as they may think best. I wish I could induce Dr. Miller, Mr. Green, the manager of the National Experiment Bee-station, and some others to take this matter in hand. Of course, that would not hinder some of us dabblers from experimenting along this line. It would indeed be funny if we did not settle this thing definitely by the time the International meets next fall. F. GREINER.

Naples, N. Y., March 12.

OBJECTIONS TO THE USE OF HONEY.

A NEWSPAPER CLIPPING FROM DR. J. H. KELLOGG, IN REGARD TO THE USE OF HONEY AS FOOD; AN ILLUSTRATION OF THE WAY IN WHICH GREAT MEN SOMETIMES MISLEAD.

The following, from Dr. Kellogg, is clipped from a newspaper, and sent us by one of our correspondents:

> Honey, in its best estate, is not a pure sweet, and consequently is open to greater objections than free sugar. The bees are not very nice in their habits, and gather their store in all sorts of places, sometimes hovering over that which is very loathsome and unclean. In gathering the nectar from flowers, the bee rubs off more or less of the pollen and carries it home with him and deposits it with the honey. If the pollen happens to be poisonous, the honey is poisoned. At Trebizond, Turkey, poisonous flowers abound so that the honey at that point is always poisonous. Further, the bee always puts in a certain quantity of poison from the poison-bag, formic acid, to preserve the honey. If the bees are very much disturbed while at their work, they inject an unusual amount of this formic acid into their product, and so the honey becomes "rank." A person who eats "rank" honey will be taken sick, and likely break out with a rash similar to nettlerash, formic acid being the poison in both instances. These facts have all been determined by scientific investigations.

We have great respect for Dr. Kellogg; but, like other great men, he has made *some* bad blunders. And, by the way, "big doctors," it seems to me, are too apt to make positive assertions in regard to things a little outside of their field, that are only mere conjecture. His expression, "Bees are not very nice in their habits," may be true in a narrow sense; but the statement is mostly misleading as it stands, as any one conversant with honey-bees knows. Again, he says, "If the pollen happens to be poisonous, the honey is poisoned." This reminds us of the fearful blunder made by the health commissioners of New York city last season in condemning grapes. They *did* see a little poison on the *stems* of the grapes, very likely; but in order to do any harm, a man would need to eat *a ton of grapes* at a meal, stems and all; and even then it is doubtful whether the quantity of poison he received would prove fatal. The honey at Trebizond, Turkey, is "always poisonous," is it? Perhaps we can find out something more about that. If there is anybody who reads Gleanings who has ever been near that locality, I would kindly ask him to give the address of some proper person, and have the matter investigated. Such a newspaper statement would be damaging to the "real-estate prospects" of that locality. We would respectfully call the attention of the Sublime Porte of Turkey to the above slanderous statements in regard to his dominion. Another thing, does the honey-bee *always* put formic acid in the honey? Prof. Cook, will you please stand up and tell us about these things that come within your domain? Some writer in some of the journals, if I am correct, once suggested that the operation of extracting honey stirs the bees up to such an extent that they inject bee-sting poison into the honey, and this is why extracted honey is more likely to make people sick than comb honey. The writer was probably working for comb honey, and felt anxious that the great public should give comb honey the preference—i. e., pay a bigger price for it. Then, again, "The person who eats rank honey will be taken sick." This is another of the positive assertions; and yet we have readers of Gleanings who eat raw honey about as friend Terry and I eat strawberries, and it does not make them sick "worth a cent." The rest of the sentence would indicate that, whenever any of you break out with a rash, all you have to do is to think back when you last ate some honey. Dr. Kellogg, you are a whole team when you go for tobacco, cigarettes, Dr. Wilford Hall, etc., but when you are writing about honey, please recognize that *it* is *not* a terrible curse to humanity that needs stamping out by such vigorous statements.] A. I. R.

RAMBLE NO. 56.

IN SAN FRANCISCO.

After a few hours' ride from Napa City we arrive at Vallejo (Val*leo*) on the San Pablo Bay. A little to the east is Benicia, where a United States arsenal and soldiers' barracks are located, and where, also, will be found one of those immense ferryboats that will take a whole train of cars. Just across the bay we come to Port Costa, where we find immense warehouses stored with wheat, ready for shipment. San Pablo Bay is but a continuation of the bay of San Francisco, and we now follow the shores of the bays for 20 miles, and soon arrive in the city of Oakland. Although Oakland is noted as being called the Brooklyn of San Francisco, it is a thoroughgoing business place, and has the motley and lively makeup seen in all western towns. It was here I saw, the first time after many months, faces that were familiar for many years in my native town. A young doctor had located here only a few months previously, and, among other household goods, had brought along his father-in-law and mother-in-law, and we all had a sort of jubilee. After answering innumerable questions about home affairs we quieted down for the night. The next day I was off for San Francisco.

It is about five miles across the bay, and the railroad piers run out some distance into the bay. The immense ferryboats are loaded every morning and evening with from one to two thousand people going from their homes in one to their business in the other, Oakland being a more desirable place of residence than San Francisco.

At the ferryway I met an old-time friend who had followed the high seas for many years in the United States navy, and had finally got settled down to punching ferry-tickets. I presented my ticket, but held on to prevent the punching. He looked at me with an angry frown, and was about to utter hot words of rebuke. Said I, "George, do you know me?" and, though 26 years had elapsed since we had met, he knew me, and so arranged his ticket business that he spent a day showing me San Francisco.

The narrow point of land upon which San Francisco is located, as shown upon the map, is fully ten miles in width; and if Rome was built upon seven hills, this city is built upon seven times seven. The surface is very uneven, and in some portions back of the city it rises to the dignity of mountains. The chief means of locomotion is by cable railroad, and it seems that any other railroad would be a failure here on account of the very steep gradients to overcome.

San Francisco has probably the most heterogenous population of any city on this continent. It has its Italian, Portuguese, Chinese, and other quarters of distinctive nationalities. The most noticeable is the Chinese, for they bring and retain all of their national characteristics and dress. The senior editor of Gleanings remarked about seeing his first Chinese woman in Portland, and noticed her head, but did not seem to notice her feet. The Chinese women that come to this country are not of the class that have those very small feet, but they wear the regular Chinese shoe, and it is a mystery how they stand on them. Nearly all Chinese wear the wooden-soled shoe; but the woman's shoe differs in being more rounding on the bottom. As they waddle along, the sole of the shoe looks like a rocker, and you expect to see the wearer pitch one way or the other. I suppose the shoe was invented by Confucius, and the people have had a long time in which to learn its peculiarities.

The prettiest sight, and one that always draws attention, is the little Chinaman of four or five summers. He is usually decked out in bright green and yellow, or other hues, with decorated shoes, and is evidently proud of his fantastic appearance.

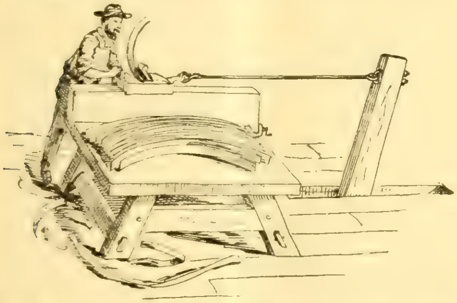
The fogs roll up over San Francisco nearly every morning, but they do not get across the bay to Oakland. The nights are cool, and a great portion of the year it is desirable to live on the sunny side of the house. There are, consequently, but few shade-trees on the streets of this city. The visitor will scarcely fail to notice the healthy and robust appearance of the women of this city, and even their faces of good rosy color and beauty.

A point of never-failing interest is to visit the Cliff House and the Seal Rocks. We run out by rail past the historical Golden Gate, and the grand Pacific Ocean is before us. We had viewed the old Atlantic from many points, and it was with a feeling of satisfaction that we were permitted to look out from this far side of the continent upon the Pacific, and see the breakers roll in upon the sandy beach.

The Seal Rocks are so named from the number of seals, or sea-lions, that congregate there. They bellow and quarrel as the waves dash over them, and one very large one, named Gen. Butler, seems to rule the roost. Sutro Heights and Sutro Park are open to the public, and it is truly a beautiful place. The Golden Gate

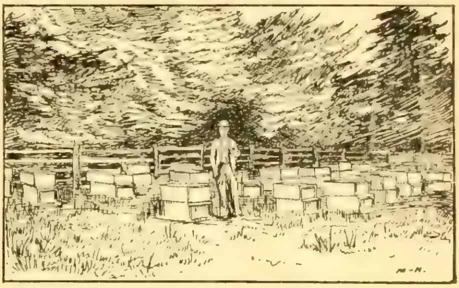
Park extends from the city down to the ocean, a distance of five miles. We walked back through the park; and, while the far end of it near the ocean is yet unimproved, the city end is a veritable paradise; and when it is all completed it will be the grandest park in the world. But space will not allow me to dwell further upon the many interesting features of this city. My friend the next morning went to the punching of tickets, and, with a letter of introduction, I sought Mr. Weston, the manufacturer of fruit boxes and baskets of all sorts and sizes. My object in looking up this business was to find, if possible, some wood on this coast that would make good sections. Spruce seemed to meet the requirements nearer than any other wood, and Mr. Weston's experience with woods of all kinds gave value to his advice. For the manufacture of baskets the material is shaved into splints from ⅜ to 2 inches in width, and of varying degrees of thickness. The machine for making these splints is very simple. The spruce plank to be shaved is clamped to a strong bench; a flat plane is operated by a strong lever that projects through the floor, to which motion is given from machinery below; a strong rope connects plane and lever, and, with a man to adjust the plane at every sweep of the lever, the plank is soon reduced to material for baskets.

Wishing to test a few shavings for sections, the plane was set to an eighth of an inch, and several strips were rapidly taken off, and the grain was not badly broken. I found, however, the following obstacles to the use of spruce: To plane easily or at all, the timber must be green or wet, just as it comes from the rafts that have been floated here from Oregon. When seasoned there is a hard bonelike film which is hard for a saw to cut unless frequent filings are resorted to. It is also more brittle than basswood when dry, and more liable to break at the corners. The price of selected timber is $30 to $35 per 1000, which puts it on the shelf as compared with basswood. Other woods have been recommended, such as cottonwood, which has only a small strip of white in a tree, and it is difficult to select it. Cedar and eucalyptus have also been recommended; but their strong odor is an objection. Sugar-pine would probably make a good section; but even that, when we select the best, is nearly the same price as spruce. Redwood is a fine wood, but the color, if not the price, is an objection. I gave up the pursuit, for I believe there is nothing on this coast or any other that can compete with basswood in all qualities for a one-piece section. Mr. Weston tried to use these splints for sections by bending and lapping one side; but they got out of shape, and looked simply ridiculous by the side of the straight and trim basswood.



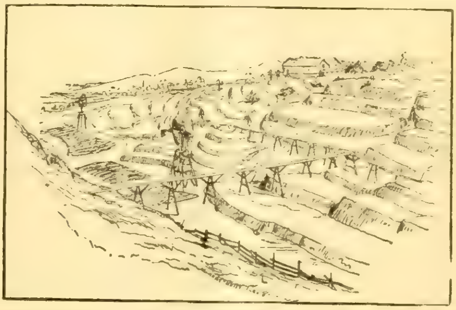
SAN FRANCISCO MACHINE FOR MAKING BASKET-SPLINTS.

Several parties have ordered machinery for this purpose, but it stands idle and is for sale. Bee-hives and shipping-crates are made by several parties here, and this can be done here as well as in the East; but still, thousands of hives come from east of the Rockies every season. The last gentleman I saw in relation to the supply business was Mr. Wm. Styan, of San Mateo, about 20 miles out from San Francisco. San Mateo is a lovely town where many wealthy San Franciscans reside in beautiful residences surrounded by shaded pleasure-grounds, and beautified with trees, shrubs, and many-hued flowers, nearly all new to the Eastern man. Mr. Styan is a sturdy Englishman, has been in the United States about nine years, and nearly all the time in California. He has an apiary of over 30 colonies, and is rearing golden Italian queens, and deals in supplies. Mr. Styan has much other business; and, his son having recently secured other lucrative business in the city, he was obliged to suspend the publication of the *California Bee-keeper* for the time being, but proposes to start it again in the near future. We traveled the shady walks of San Mateo a while, during which Mr. S. pointed out bees at work on the small white blossom of the eucalyptus-tree. I was informed by Mr. S. that this honey is much sought after on account of its medicinal qualities. The blossoms are very fragrant, and it is a healthful tree to have around. Mr. Styan's apiary has the eucalyptus for a background. In San Mateo are several educational institutions, and, on the whole, it seems to be a desirable place in which to reside.



A EUCALYPTUS APIARY.

Between San Mateo and San Francisco, gardening is extensively engaged in. The side hills are neatly terraced, and water drawn up by scores of windmills to irrigate and make productive all the long year round what otherwise would be a barren hillside.



TERRACING, AND IRRIGATING BY WINDMILLS

After my return to Frisco I felt a strong desire to test the merits of ocean travel; and upon the steamship Queen, bound for Southern California, will next be found the RAMBLER.

[Yes, friend R., I did notice particularly the wooden shoe worn by the Chinese women, and their peculiar walk; and Mrs. Root and I both admired the Chinese juveniles. They are by all odds the cutest and prettiest members of the Chinese family; and how in the world these Chinamen can stay here in our country without their liitle ones, to say nothing of their wives, is beyond my comprehension. I saw some little fellows carrying in wood, and doing other chores about the house, and they seemed to be as deft and handy, almost, as the grown-up ones. It seems we went over about the same ground, and we were especially interested in Sutro Park and Sutro Heights, and the seals. You call them "sea-lions." Well, it seemed to me that some of those big fellows were something more than large seals.—It seems to me your machine for making basket-splints is a rather primitive one. Can they not get better tools from some of our Eastern manufacturers? Your investigations in regard to material for making sections just about agree with our own here.—In regard to the *California Bee-keeper:* I do not know that it is our business to stir up discord; but it occurs to me that Mr. Styan and his son, when they found that they had too much else to do to keep the *Bee-keeper* going, should have refunded the money for which no equivalent had been rendered. I mention this because I heard considerable complaint along this line; and if the matter is not fixed up, people are going to be a little slow hereafter in subscribing for new bee-papers.] A. I. R.

THE PORTER BEE-ESCAPE.

A GOOD TESTIMONIAL FOR IT; BEES' WINGS NOT TORN BY IT.

In response to your request concerning the Porter spring bee-escape tearing bees' wings, I wish to say that bees' wings are not injured in the least in passing through the escape. Although I have used these escapes ever since their invention, and having no occasion to mistrust any injury to the bees in any way, upon reading your editorial I made further investigation. Having a few springs, such as are used in the Porter escape, I tried cutting or tearing bees' wings with one of these springs, and found it almost impossible to mutilate the wings, even when holding them between the thumb and finger of one hand, and using the spring as a knife-blade or punch. So tough and flexible are the wings of bees, that they slip aside in spite of any effort to hold them in position to tear them. I also caught a bee and brought it to a window, and compelled it to pass through an escape several times, watching it closely while doing so; and should you make an experiment of this nature, you would doubtless say, "*Nonsense!*" I think that no intelligent bee-keeper would expose his ignorance by intimating that bees' wings are injured by passing between the springs of the Porter escape. Much less would it be likely that an intelligent gathering of bee-keepers would pass a verdict of condemnation in matters of this kind without thorough investigation; so I think there must be some mistake in this matter. Furthermore, it does seem that, where so many prominent bee-keepers, such as Prof. A. J. Cook, J. F. McIntyre, Thomas Pierce, John S. Reese, J. H. Martin, and many we can not mention, have given such hearty commendations of this useful implement, the matter as mentioned in your editorial could not be very serious, or some one would have discovered it ere this.

If all the appliances of the apiary were as faultless as the Porter escape, bee-keepers would have but little to complain of in the matter of fixtures. S. A. Shuck.

Liverpool, Ill., Mar. 10.

[We have had enough now to prove that the rumor of wing-tearing was founded on mistake If any thing has been called out it is that the Porter is a good thing.]

THICK VS. THIN FOUNDATION FOR SECTION HONEY.

THE ONTARIO AGRICULTURAL AND EXPERIMENTAL UNION DECLARE IN FAVOR OF THE EXTRA THIN FOR SURPLUS.

The following printed report came through the mails; and as it records a valuable experiment we take pleasure in copying it:

The experiment conducted was, "Testing to what extent, if any, the bees thin out the septum, or base of comb foundation before storing the honey in the comb, and what effect various thicknesses of foundation have upon the thickness of base finally left by the bees." The object of this was to see if heavy grades of foundation would leave an undue amount of wax in the comb, making it unpleasant to the consumer, and injuring the sale of comb honey; or if it might be drawn out into cell walls by the bees. The foundation was supplied free of all charges to the ones agreeing to conduct the experiments. There were three grades sent out, being 6 feet to the pound, 10 feet to the pound, and 12 feet to the pound, known as medium brood, thin surplus, and extra thin surplus. The sections were marked accordingly before putting into the hive, and instructions given to place all over center of brood-chamber to give all an alike favorable position or otherwise for drawing out and building on the foundation. Owing to the very unfavorable honey season generally, some were unable to get the foundation drawn out at all. These we hope to secure next season. In testing for sections which had the thinnest base, the three samples were taken without looking at the number of feet per pound marked on wood, and by looking through base of section and taking a piece of each comb in mouth, the order of thickness was found, and in almost every instance the order was the same as when the foundation was placed in the sections. In no case was the least difficulty experienced in discovering that the foundation 6 feet to the pound was the heavier—the base and also the wall was heavy; and the feeling, when eaten with honey in the mouth, decidedly unpleasant. In No. 8 experiment a heavy honey-flow was secured artificially, by putting a feeder on top of the hive, holding about 15 pounds, and the bees built the comb out very quickly. In this lot, when the honey was extracted and the wax was cold, the cell wall built on by the bees was broken away, and underneath the foundation was found in almost if not exactly the same condition as when put in the sections. The general results tend to show that comb foundation in sections is not thinned by bees as is generally supposed. Twenty-four applied for material, out of which the following number reported, as follows:

BY WHOM CONDUCTED.	POSTOFFICE.	HONEY-FLOW.	ORDER OF THICKNESS.		
			6 ft.	10 ft.	12 ft.
1 Dr. Geo. Duncan*	Embro, Ont.	Light.	1	3	2
2 E L Goold & Co	Brantford	Medium.	1	2	3
3 Geo. E. Adams....	Brantford.	Medium.	1	2	3
4 Wm. Mobray	Sarnia.		1	2	3
5 Elg'r M Husband	Cairngorn.	Medium.	1	2	3

11 W. Haight....	Wellington.	Medium.	1	2	2
12 Jas. Shaw	Kemble.	Medium.	1	2	3

*A scarcely perceptible difference between 2 and 3.
†A very marked difference.

Apiarian Committee. { Edgar M. Husband.
W. Haight.
R. F. Holtermann.

[If we understand the report correctly, the result of the experiment seems to favor extra thin foundation; but a number of bee-keepers on this side, Dr. Miller, the Dadants, and some others whose names we do not now recall, have decided that the "extra thin" is no better, nor as good, as what is called "thin surplus." When the matter came up for discussion, we believe the objection to the extra thin was, that the bees would, on account of its extremely light weight, sometimes gnaw it.]

EMPTY COMBS AND OLD FOUNDATION IN SECTIONS.

SECTIONS OF OLD DRAWN COMBS VS. SECTIONS OF FRESH FOUNDATION, ETC.

As the bee-keeper goes to work to prepare his supers for the coming harvest he is often met by the problem what to do with the unfinished sections left over from the previous season. As to the value of such sections for using again, the widest difference of opinion prevails. Some consider them superior to freshly filled sections, and fill whole supers with them, while others consider them worse than worthless except for the purpose of attracting bees into the supers; and even for this purpose they do not want more than one or two in a super.

When the subject was first brought up for discussion, several years ago, I received many appreciative letters from those who had found, as I had, that it was more profitable to melt up sections filled with comb than to try to have them filled with honey. But there were some very practical honey-producers who opposed this view, and continued to oppose it in a way that was at first very perplexing to me. I had found that sections were never first class in appearance, and that, while the bees might begin work on them first, they would not be finished as soon as those started from fresh foundation. It has been generally conceded that such sections never look quite as nice; but the proposition that they are less valuable otherwise has always been opposed.

During the past two or three seasons, with their poor yields of honey, I think I have found the reasons for this difference of opinion. I have found, as others have, that, during a very light yield of honey, the two or three "bait sections" of empty comb in each super would sometimes be filled with honey, and finished, before sections containing foundation had been started at all. Of course, under such circumstances the use of sections containing drawn comb would give a larger yield of box honey, even though its quality might not be first class. But it is to be hoped that honey-flows of so light a character as this are not going to be frequent enough to make it necessary to take this point very much into our calculations.

When we closely question many of those who insist on the great value of drawn combs in sections we find that they use only starters of foundation instead of sheets filling the section full. A comb reaching from top to bottom of the section offers much greater inducements to the bees than a narrow starter at the top, and good combs may be more profitable than such starters.

But the principal reason why many do not see this question in its proper light is, that they do not compare the sections of drawn comb with those filled with *fresh* foundation. I have known for years that freshly made foundation is better than that which has been exposed to the air for some time, but I never saw the difference so strikingly shown as in an experiment last summer. On account of lack of help, many supers were just as they had been left the preceding summer, the sections containing full sheets of foundation untouched by the bees. Wishing to try a new make of sections, two or three rows of the old sections were removed from each of a number of supers, and replaced with the new ones containing fresh foundation. Only a moderate amount of honey was being gathered, and but few colonies were making any progress in the supers, so that I was surprised, a couple of weeks later, to find most of those new sections built out and finished, while in some cases the old foundation, right alongside in the same supers, had not been touched.

If, in testing this matter, full sheets of fresh foundation were always compared with drawn combs, I think the unprofitableness of the latter would seldom be questioned. But there is a serious difficulty in the way here. It is not always possible for the bee-keeper, especially if he counts his colonies by the hundred, to use only fresh foundation. He must prepare many of his supers in advance of the honey-harvest, and is always liable to have some of them left over unused. If he does not do this he must be able to count on an abundance of reliable help during the honey season, or he is liable to serious loss. On the contrary, I am convinced that he may lose heavily by using old hard foundation. Between the two horns of the dilemma I hardly know which to choose. What I have decided on for the present is this: All drawn-out combs, except enough of the best to put two or three in each super, used at the beginning of the season, shall be cut out and melted; all sheets of foundation that have become bleached or propolized shall be remelted, and at least one-third of the sections in each super shall be filled with fresh foundation. By "fresh foundation" I mean that which has been exposed to the air as little as possible, and has not been put into the sections more than two or three weeks in advance of the time it is needed on the hives. Possibly it might not deteriorate very much by being in the sections a couple of months; but that which has been kept over from one season to another, exposed to the air, is certainly very far inferior to fresh foundation. This is especially the case when it has been on the hives some time and has been varnished over with propolis by the bees.

I consider that foundation best which has come most recently from the dipping-tank and rolling-mill; but that which has been papered and tightly boxed, so that it is not exposed to the air, will keep a long time with but little injury.

J. A. GREEN.

Dayton, Ill., March 4.

PREVENTING INCREASE WHEN THE FIRST SWARM ISSUES.

J. F. M'INTYRE EXPLAINS MORE FULLY THE SECRET OF THE DADANT NON-SWARMING PLAN.

In Chas. Dadant & Son's article on preventing increase, page 541, 1891, they revealed a secret not found in the books; at least, I have just looked through ten bee-books, Dadant's included, and did not find it in any of them. They all agree that, as a rule, the first swarm issues when the first queen-cells are sealed, unless prevented by foul weather. Now, every bee-keeper should know that there are several other conditions which will make a colony postpone swarming until the second crisis, that is, when the first cells are ready to hatch, and one of the most powerful is a large hive containing plenty of empty combs. If I understand Dadant's system they put a super full of empty combs on their extra large brood-chambers before the bees commence to build queen-cells, or get the swarming fever; this prevents most of the colonies from getting the fever, and the few that start queen-cells do not swarm until the first cells are ready to hatch. In that article they say, "If we return the swarm 48 hours after swarming, the queen-cells have been destroyed by the young queen, and the bees get rid of her or the old one when the swarm is returned." This shows that they mean the first swarm, and that their bees do not, as a rule, swarm until the first young queens are ready to hatch. They probably would not have any swarms if it were not for this crisis; the bees seem reluctant to kill the young queens, for, as a rule, the old queen is feeble, or they would not have started the cells, so they yield to the impulse and swarm. If the weather happens to be unfavorable at this time, one of the young queens will often hatch, and kill the old queen, when the swarm will issue with a virgin. I had 109 first swarms this season, and out of that number 49 killed the old queen and swarmed with a virgin; 40 swarmed with the old queen when the first cells were ready to hatch, and 20 according to rule, near the time that the young queens are sealed over.

I am afraid that bee-keepers having small hives will be seriously disappointed in trying Mr. Dadant's plan of preventing increase, because, as a rule, bees in small hives do swarm on the sealing of the first queen-cells. I feel very sure that the success of the plan depends on having a large hive filled with empty combs, or, rather, the super filled with empty combs. You may put it down in the books, that a colony having a large amount of empty comb in their hive will not, as a rule, swarm until the first queen-cells are ready to hatch; and that such colonies, when they do swarm, are very easily discouraged from swarming again. The exigency of the case forces them out against their better judgment; and when this exigency is removed by one queen hatching and killing the others, the bees are contented to remain.

Fillmore, Cal., Feb. 24. J. F. McINTYRE.

[Friend M., I entirely agree with you in the position you take; and since you mention it, I feel pretty sure that a large hive like the one used by the Dadants would have very much to do in keeping down the swarming fever; but I am afraid, my good friend, when you looked over those ten bee-books you did not look very carefully—that is, if the secret you speak of is the matter of giving a larger amount of room and empty combs. In the A B C, under the head of "Prevention of Swarming by the Use of the Extractor," you will find particular emphasis placed on this point. See also Dadant's book, paragraphs 461 and 459. I am glad, however, that you have called attention to it, for perhaps it has nowhere been stated with sufficient clearness. Putting on a whole super filled with empty combs, just before the bees get the swarming fever, will surely do very much to hinder swarming. For many years I have watched and experimented, with a view of getting at the real cause of swarming; and when they really get the fever, it is oftentimes a pretty hard matter to stop them. I remember of once seeing some motions among the bees in a hive I had just opened, that seemed to indicate they were getting ready to swarm. I hastily lifted the combs, and stood them up against the grapevine trellises, so as to scatter them several feet apart. If I am correct, I had got them so placed that no two combs were together, and yet these bees started the swarming-note, and commenced rising from one comb and then another; and finally all that could fly left their combs and united in the air. So I concluded that, when bees had once made their arrangements, and got the real swarming fever, it was not an easy matter to hold them back.]

A. I. R.

ECLIPSE FOUNDATION-ROLLER.

HOW J. M. HAMBAUGH FASTENS HIS FOUNDATION TO THE TOP-BAR, AND IMBEDS THE WIRE.

Well, well! It does really seem strange to me that so simple a little device as the "Eclipse foundation-roller" should have remained so long in obscurity, and its merits so little known in the bee-world. It is certainly very simple, and yet it is perfection in the direction for which it was designed. Necessity is said to be the mother of invention, and it was after being thoroughly disgusted with all the methods known to us for putting foundation securely and rapidly in frames that led to the discovery of the roller; and now I am bound, in justice to a former friend and partner, by the name of Stone, to give him credit for the first invention of this practical little device. The original is still in my possession, a picture of which I herewith submit.

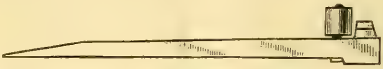

FIG. 1.—STONE'S ORIGINAL ROLLER FASTENER.

Mr. Stone left the State and embarked in other pursuits shortly after this; and while the roller of our present device is practically the same as that of the original, I have materially changed the shape of the handle and the mode of adjusting the roller to the proper depth on the brood-frame. We found the roller a grand improvement, and with a little practice we could put the foundation starters in very rapidly.

It was about this time in our experience that we became somewhat familiar with the methods of the Dadants; and having adverse experience with the use of starters in brood-frames we began to pave our way for the use of full sheets of foundation in brood-frames; and this, of course, called for wired frames. We accepted them as authority upon the subject of wiring, and commenced wiring in accordance with their method, and as illustrated in GLEANINGS for Jan. 15. The roller, as illustrated on the same page, 50, I presume was devised for beveled-edged top-bars, which must be differently constructed from the ones we use in our work. We cut all our top-bars ⅞ inch square, as will be seen by our illustration.

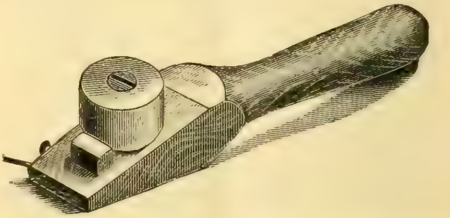

FIG. 2.—HAMBAUGH'S IMBEDDER AND ROLLER FASTENER.

We soon discovered that the roller of itself was of but little value to us in putting in full sheets of foundation without some device to imbed the wire into the septum of the foundation. Here, again, necessity became the mother of invention; and while friend Dadant has refused to recognize our device as of any practical utility, I want to brand him as a Frenchman. I have never used any thing else, neither have I had cause to wish for any thing better in my entire experience in bee-keeping, and I have thousands of combs in use to-day in which the wire was imbedded with our device, and I defy him to find a flaw in their construction. It is simply a small one-inch wire nail set in a handle at an angle, as in cut No. 3. The head is filed off, and a groove set in the point running lengthwise with the handle. It is operated by setting the groove in the pointed instrument over the wire furthest from the operator, as in cut No. 4, and, with a slight pressure, pull toward you, and thus press the wire into the foundation the depth required. Our friend Mr. Dadant, I believe, claims that it tears the cells of the foundation too much. I certainly think he has not given it a practical test. I know that, while the grooved wire may make a slightly wider track than the spur-wheel or Carlin tool, it matters but little to the bees, as it is soon drawn over, and the wire is buried as perfectly and securely with the work of the wire-imbedder as that of either of the more expensive tools. Later years we have attached the wire-imbedder to the corner of the foundation-roller (see cut No. 2), which is an improvement over the old method, inasmuch as it saves so much extra handling of tools while doing the work of putting in foundation, etc. The only advantage that we can see in the spur wheel is, that the wire may adhere a little firmer to the foundation while the frames are being handled; but we have had no trouble from that source with our method, except when we have transported combs in wagons to out-apiaries; and where this is required we now take our tools and foundation along and put the foundation in after arriving at the yard. As regards our mode of wiring frames, I believe it to be the most economical; and where care is taken to wire the frames properly, and the wire is drawn sufficiently tense to sing, there can be no better method adopted.

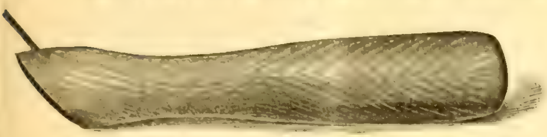

FIG. 3.—HAMBAUGH'S WIRE-IMBEDDER.

HOW TO MAKE THE PLATFORM.

Our method of using the roller and wire-imbedder is as follows: Should you be using the standard Langstroth frame, dress up an inch pine board, 22 in. long by 12 in. wide. Nail cross-pieces 12 in. long by 2 inches wide and 1 inch thick across each end, as seen in engraving No. 5. This is for the purpose of preventing the board from curling. Now dress down a piece of sheeting, the dimensions of half the thickness of the frame. Should your frames be $\frac{7}{8}$ in. thick this piece should be $\frac{7}{16}$ of an inch, and cut so that, when your brood-frame is laid upon the platform, the piece should fit inside of the frame, but not too tight. Give $\frac{1}{8}$ of an inch play all around. Now place your frame in the center of the platform, and put the $\frac{7}{16}$ piece inside of the frame, and nail it to the platform with inch wire nails, or 3 penny fine.

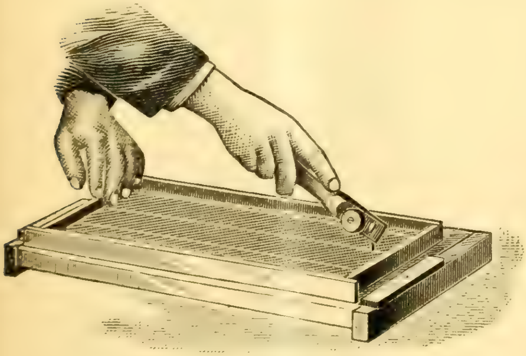

FIG. 4.—IMBEDDING THE WIRES.

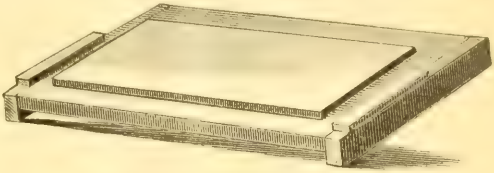

FIG. 5.—IMBEDDING-BOARD.

Now raise the frame from the bottom side, leaving the top-bar down, as in cut No. 6. Now tack a strip at each end, as can also be seen in the cut, to hold the frame from sliding, and you are ready for business. See cut No. 5.

HOW TO PUT THE FOUNDATION IN THE FRAMES.

Place a brood-frame on the platform, top-bar down. See cut No. 6. Now place your sheet of foundation on the platform, and slide the edge a little past the center of the lower side of the top-bar. With your thumb, press the wax into the wood at the center and ends; now bring light strokes back and forth, increasing the pressure as the wax adheres to the wood, until you know it to be sufficiently stayed. Now bring your frame down over the close-fitting $\frac{7}{16}$-inch raise, as in cut No. 4, and place the groove of the wire-imbedder on the wire at the opposite end of the frame (see cut), and, with proper pressure, pull to you, and you can soon give the wire proper depth in the foundation. Of course, practice makes perfect; but, my word for it, you can soon do your work neatly and rapidly; in fact, it is real fun, when you once get up to the business. The roller-mill needs dipping in water occasionally.

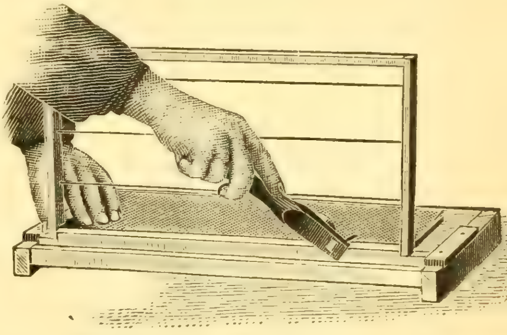

FIG. 6.—IMBEDDING FOUNDATION TO TOP-BAR.

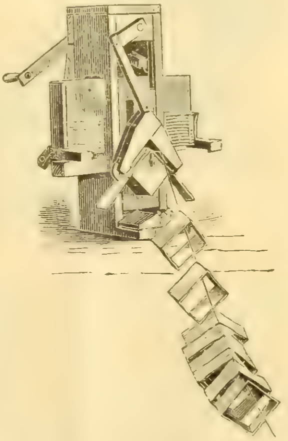
Spring, Ill. J. M. Hambaugh.

[While we may be under lasting obligation to your partner, Mr. Stone, we are under equal obligation to you for improving and making public so good and useful a device. Yours, as you say, is adapted for fastening foundation to the top-bars, the under side of which is flat, while ours is made for the molded comb-guide frames. And now about that wire-imbedder. At first we were inclined to agree with our mutual friend the Frenchman; however, before passing an opinion we decided to make such a tool and try it. Upon trying it we were greatly disappointed—not because it *didn't* work, but because it worked so well. It will imbed the wires very rapidly; and one pleasant feature of it is, that the grooved nail does not run off from the wire as some of the spur-wheels do occasionally. It has, however, one objection; and, as your friend Mr. Dadant states, it tears the cells of the foundation a little too much. But all of this, we presume, will be readily fixed by the bees when honey is coming in at a good rate. But sometimes the bees are disposed to gnaw around the wires, and the grooving or creasing of the nail might make them more disposed to gnaw. We therefore believe that the spur-wheel, such as is recommended by the Dadants, will generally be preferable because the wires are imbedded so nicely that it is almost impossible to detect the track of the wheel; and while your implement has the element of cheapness and simplicity to their fullest extent, the spur-wheels cost but little more, and, we believe, would give more satisfactory results.]

PHILO'S AUTOMATIC SECTION FORMER AND GLUER COMBINED.

A NEW MACHINE BY E. W. PHILO.

For quite a number of years past, perhaps ten or more, I have felt the need of a machine for doing more rapid work in putting together and gluing sections, during which time I have made several devices for accomplishing this work, but have never been fully satisfied with any of them until I had completed and thoroughly tested the one we place before you in the accompanying cut.



FOLDING AND GLUING SECTIONS BY THE WHOLESALE.

Although I have made two other machines in the past year that would do the same work, they were much too expensive to come into general use with the average bee-keeper. My aim for the past year has been for a machine that would do the whole work without any hand work, except filling the machine up with section strips and turning the crank. Every man, woman, and child knows how to turn a crank, and that is all that is required to operate the machine; and when that is done, out comes the section, all glued, folded, and pressed together — one every two seconds, or thirty every minute, by turning the crank moderately. To give you an idea of the amount of power required, my boy Ernest R., four years old, can operate the machine nicely. When the crank is raised to the highest point, the slanting board at the back of the machine is pushed in, and there are two little horizontal sticks fastened to the end of the board that pushes the bottom one of the section strips out over the block to be folded. The folding block then comes down folding the first joint, as you will see in the cut. The upper part of the little claws comes down on top of the section, causing the lower ends to turn in, bringing the ends of the sections together. The whole block and all, which is held up by a spring, goes down until the section is forced together in the V groove at the bottom. The two little blocks in the V groove are to make the ends of the sections come right, so they will go together easily; and while the section is being pressed together the gluer comes up out of the glue and puts some glue right in the V groove, and on the end of the section where it is dovetailed. E. W. Philo.

Half Moon, N. Y., Feb. 29.

[We have not seen the machine yet, and consequently are unable to judge personally of its workings. Mr. Philo is quite a genius in "making things," and we have no doubt it will do all he says it will. We should like to have reports from those who have tried it.]

"STRAWS" FROM CALIFORNIA.

COMMENTS ON STRAWS AND OTHER THINGS IN GLEANINGS.

Say, doctor, don't you think the big New York bee-men alluded to in Stray Straws of Feb. 1 are very practical, sensible fellows in not reporting their crops? The fact that they are the *big* bee-men of New York strongly tends to prove they are likely to have good reasons for so acting. Apply your suggestion as to giving legal control of their territory to other businesses, and see where it leads. Can you give any good reasons applicable in case of the bee-men which may not be just as equitably used by others who may wish to keep away competition?

Conflicting advice.—Another straw in same bundle says, "A. I. Root better come home and see to those boys," and then one of "those boys" is advised in the next lot of Straws to "keep A. I. down in Florida and Cuba till settled warm weather." Second thoughts are often best, doctor.

So the Hon. R. L. Taylor has no regular medical education. Forewarned is forearmed; but if the health of the weather is not what it should be it will probably not wish to be tinkered up by a miller, so will save the dollar.

And now you are "beginning to get mad." Don't do it, doctor, but try a quart of that drink mentioned on page 8, which J. A. Green does not seem to understand. Let J. A. make it, then he won't ask what the yeast is for. It's splendid for acting on the brain.

T. V. Jessup deserves sympathy in his efforts to obtain subscribers to Gleanings. Whoever Uncle A. I. may be, he is awfully behind times if he does not subscribe. Let us hope this may reach his eye; and next time he is asked to subscribe, let him hand over his dollar like a man.

Mr. Rambler, the picture of your meeting with the socialists in Chicago is highly interesting. How did you manage to get into Riverside? They are very particular about preventing the entrance of insect pests there, and have officers appointed to destroy all such. You'd better see them. And, Mr. R., what lazy men they are in Indiana to let the women do the hard work of pitching the hay on the wagon, while the men ride and gently arrange it!

Miss Wilson deserves thanks for her explicit instructions for making candy. When she starts in to explain a matter, she manages to convey a clear idea of what she has in her own mind. Many folks can not do so (that includes me).

What a blessing that that spring Mr. Root depended on to get his toes clean was able to maintain its reputation for detergent qualities!

But there is a limit, even to the powers of our California springs, so don't try them too far, Mr. Root, *please*.

Say, Mr. Editor, if I keep on kicking around in the apiary in this manner, disturbing the hives, I'll be getting pretty badly stung, and serve me right—durned fool.

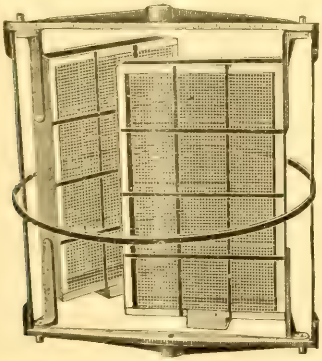
These sundries belong to what Mr. Doolittle terms "the fun" part our "profession," and I'm going to see what becomes of them before committing any more to the tender care of an editor. I don't take much stock in editors: they don't treat me well, generally; but as you, Mr. Editor, are young in the business (having been at it only five years, and not a few weeks only, as Mr. Hilton seemed to imagine), you have probably not become callous and hard-hearted, and so I may perhaps obtain more gentle treatment at your hands; but if you kill me, do it quickly. Now I'll stop. But what a lot of paper it takes when one is allowed to use only one side! but it's your loss. I could have written twice as much if I used both sides.

[No name was signed to the above; and, as a rule, we reject all communications without a signature; but we shall have to break our rule this time, because—well, because the subject-matter is quite "available." Come again, Mr. What's yer Name, but only let us know who you are.]

THAT COWAN EXTRACTOR.

HOW TO REVERSE THE BASKETS WHILE IN MOTION WITHOUT REVERSING THE CRANK.

Just why I should be very much interested in extractors I hardly know, seeing I use one so little; but any thing new in that line always excites my interest; and when Ernest told me about the Cowan extractor on my last visit there, it was not long before I was amusing myself trying its capabilities. And then I made what Ernest is pleased to call my "discovery," that the comb-baskets could be reversed without entirely stopping the motion.



THE INSIDE OF THE COWAN EXTRACTOR.

The trick is a very simple one. While the right hand is in use turning the crank, with the left give a push against one of the baskets to carry it beyond the center, when centrifugal force will take it the rest of the way, and then treat the other basket the same way. You must "slow up" to do this, for the left hand is not quick enough to do it under full motion. Still, with a little practice I found that I could make the proper push with the left hand without slowing up so very much. A piece of plank was in each basket, making it work about the same as with a pair of heavy combs. I was really surprised at the ease with which the baskets could be reversed.

I am not very well posted in all kinds of extractors; but from what little I have tried automatic extractors, I should prefer the Cowan. I know that the thought is likely to be, that an automatic machine works itself, and consequently requires just so much less labor. But if two machines that do the same kind of work are compared, I think we shall prefer the one that, on the whole, works best with the least labor. In any automatic extractor that I have tried, the automatic part is hardly automatic in the strict sense of the word, for it requires care and some skill on the part of the operator to accomplish the reversing. True, it is done with the hand that turns the crank; nevertheless, it is a fact, I think, that, in the hands of an inexperienced person, the simple act of reversing the motion does not of necessity reverse the baskets. I think it requires less skill to run the Cowan, and that one learns to run it in less time. Moreover, it requires less time to reverse the Cowan. The automatic must come to a dead stop, and the motion must be reversed. The Cowan does not stop—merely "slows up" for the left hand to do its part, then resumes its former speed.

I can not say how it may be with others, but for me it is much easier to turn a crank that moves in the direction of the hands of a clock than to run it in the opposite, or what might be called backward, direction. In running the automatic, when the baskets are reversed the motion is reversed, and of necessity you half the time turn the crank backward. With the Cowan, no change of motion is made; and, no matter how many times you reverse the baskets, you continue to turn the crank all the time forward, unless you prefer to turn it all the time backward.

Possibly, if I were more familiar with the matter my views might undergo some change; but it seems to me that the main principles which I have mentioned would remain much the same. But it must be remembered that the Cowan runs only two combs at a time. To make a four-comb Cowan, I think the can would have to be very much larger than that of a four-comb automatic.

CONTRACTION IN HARVEST.

A correspondent from far-off "bonnie Scotland" wants me to say whether I have come to any settled conviction concerning matters mentioned on page 66, in "A Year Among the Bees." I can hardly say that I have come to any settled belief as yet; but I became so little satisfied with any vacant space under the super, that, for some time, I have left eight frames in the hive the year through. Aside from any thing else, there is one very serious objection to having any thing like a vacant space under any part of the super. The bees positively refuse to do as good work above any thing except brood-combs. I have tried it having all closed up carefully under the part that contained no brood-combs, and I have tried it with an open space under; but for some reason the sections directly over the brood-combs are worked the best; and I should want a good deal of advantage in some other direction to balance this.

Moreover, I don't feel so sure as I did, that, in the long run, there is any gain in limiting the laying room of the queen. I know what some will reply, and I can reel you off a very pretty theory about not having a lot of idle consumers reared which will have nothing to do, but I haven't been able to see that the bees gave as much respect to the theory as they should, and it's a good deal less trouble to keep the same number of frames in the hive the year round. If you take away part of the frames at time of honey harvest, they must be taken care of till later, and then they must be got back again, and it isn't certain that the brood-nest will be in as good shape for winter when combs are put in late as when they have been left there throughout the season.

In the case of those who allow natural swarming, the case may be different. I can not speak from actual experience. It certainly looks as though for a time after being hived, a new swarm with limited brood room should do excellent work in the super. I think this is claimed by those who ought to know. But it is possible that some of the after-results are not just such as would be most ardently desired.

I am also asked to tell the size of my frames. The most of them are 18x9, outside measure. I wish that they were ⅜ shorter and ⅛ deeper—not that I think any noticeable difference in the working of the bees would result, but 17⅝x9⅛ is a standard size in this country. I am gradually working into the standard size with Dovetailed hives. If I were in Scotland I should likely use the standard British size, 14x8½.

If I should give the address of my correspondent, I am afraid there would be an exodus of bee-keepers from this country to settle about him. Just listen to this benighted hea—I mean Scotchman. He says, "I am a Scotch farmer, and work 50 colonies of bees during spare moments from farm work. I never saw an apiary but my own, and never had personal instruction. What I know about bees is from reading. . . . As I am situated among the bonnie heather-clad mountains, my main crop is heather honey, for which I get from 1s. to 1s. 6d. (25 to 37 cents) per pound section. . . . . I have never yet been able to supply all orders, and am therefore sold out as soon as removed from the hive." Just think of 25 cents a pound, with an unlimited market! Wouldn't I just like to pounce down on that Scotchman some day, in his mountain fastness! C. C. Miller.

Marengo, Ill., Mar. 21.

[We reproduce the cut which appeared some two months ago, in order that our readers may more clearly understand the operation that Dr. Miller is describing. Perhaps in answer to the last paragraph we ought to state that it is not practicable to make the Cowan a four-frame extractor—at least, with frames as large as the Langstroth. We have a two-pocket machine—each pocket wide enough to take in two Heddon combs. If any one desires a *four*-frame Langstroth reversible extractor, he had better purchase the Stanley. In our opionion this is the best automatic reversing extractor for four Langtroth combs. For the majority of bee-keepers the two-comb reversible Cowan would answer every requirement. One has only to try it to determine how much more rapidly it can be operated than the ordinary two-comb non-reversing extractor.]

THIN VS. THICK, OLD VS. FRESH FOUNDATION FOR SECTIONS, ETC.

EXPERIMENTS THAT ARE TO BE CONDUCTED BY THE DEPARTMENT OF APICULTURE, AT THE MICHIGAN AGRICULTURAL COLLEGE.

It has seemed best that the experiments here should be along the line of practical work in the apiary. As bee culture has been my occupation, and as I have never had the opportunity of special scientific training, practical experiments seemed to me to open the surest way in which I might be of benefit to the bee-keepers. Practical work in experimental science, or the practical proving and testing of scientific truth, has been most valuable, especially when directed toward that great subject of recent scientific research, agriculture, and its allied branches. If the material development of bee culture can be assisted by these practical experiments, it seems to me that more will be accomplished than if purely scientific—or, rather, theoretical—lines of work be considered.

With this in mind I have undertaken to work this summer upon a number of experiments of considerable practical interest. I have chosen to speak first of the one described below, because preparation for it should be begun immediately, and because I desire some help from others. This subject is one in which I am interested, and about which much more than we now know might be learned. There are many subjects in bee culture, our knowledge of which is based on suppositions, on single observations, or upon dogmatic statements that are allowed to be repeated continually in our bee-journals. Our bee-keeping literature is so full of this that we are nearly all continually falling back upon these facts (?) to find a basis for argument that often leads to serious error. There is much of this, it strikes me, in our knowledge of the use and abuse of comb foundation. The improvement in the methods of manufacture, and in the perfection of this product, have kept pace with our knowledge and experience, and even gone further. It has been supposed that the side walls of comb foundation should be high and soft, and the base very thin; and the manufacturers have accomplished this. Again, when the flat-base foundation was introduced, being much thinner than any before made, it was said that, therefore, it was best to use it, as less "fishbone" in comb honey resulted. If foundation in sections is worked or drawn out by the bees as much as is commonly believed, why should there be more fishbone in honey when the heavier foundation is used? The experiment in Ontario last year with comb foundation seemed to point with emphasis toward the fact (?) that bees do not thin the septum of foundation according to tradition. I should like to see this experiment continued to foundation 14 ft. to the pound, both natural and flat base, and under more varied conditions of climate and honey-flow. The flow in the experiment above was in all the cases, with one exception, light, and in that case the flow was artificial. The experiment that I have in contemplation extends the work to flat and natural base foundation of both 11 and 14 ft. to the pound, combining and alternating so that there may be numerous checks upon the correctness of the work. The relative worth of these weights and kinds of foundation will thus be tested, not only to determine the comparative extent to which the foundation is manipulated by the bees, but to discover which variety gives to the finished product the finest appearance and best combs for shipping. In a poor season we suppose some kinds of foundation are not worked as readily as others, but are often gnawed away to be rebuilt imperfectly if at all during subsequent flows.

Starters will be compared with full sheets of foundation, and by photographs and measurements the relative appearance of the finished combs presented, as well as the weight or quantity produced in each manner.

Southern wax is said to possess certain properties peculiar to itself, rendering foundation made from it more brittle, and thus less liable to be drawn out by the bees. The attempt will be made to discover whether this difference is real, or whether it exists only in report.

Old foundation is said to dry or harden in such a manner as not to be acceptable to the bees. This foundation, both one and two years old, will be compared with new and fresh foundation. The extent of injury done by using this old foundation will be estimated by a comparison of the amount and grade of honey produced.

Of course, these experiments will depend largely upon the season for the value of their results, which in a good season would be very different from the results during such a season as last year. They each would in their place be valuable. It would be very interesting and valuable to compare the results to be obtained during various seasons and in various localities, and with various races and strains of bees.

With this end in view I have made arrangements with one of our well-known foundation-makers to supply the required foundation to a number of bee-keepers in various localities. I should like one person in the East, one in the lower Ohio River Valley; one, say, in Nebraska, and one in Wisconsin or Minnesota, and perhaps one in the irrigated region of the West, to signify their willingness to help me in this. It will not cost a large amount in either time or money in any apiary run for comb honey. On the other hand, although it will require some care it will, I hope, be interesting to the bee-keepers undertaking it, to observe personally the results of the experiment in one case. I will forward full directions and blank forms to render the work more exact and simple, with detailed explanations, to those who are selected from the various localities. It will require about 25 supers to contain all the foundation and combs used in the experiment, so that at least 25 colonies are necessary. The experiment will probably not affect the amount of honey to be obtained from these colonies.

Prof. Cook has suggested to me, with regard to the above, that an exhibit at a fair, of the honey obtained in this experiment, would be very interesting and instructive to bee-keepers. It could be labeled, "This 25 lbs. of honey was produced upon starters of foundation only;" "This upon foundation 14 feet to the pound;" "This in empty combs left from last year," etc. Bee-keepers interested in fair exhibits of honey will, of course, take the cue as to the possibilities in this line. I wish to hear from those interested as soon as convenient, that arrangements may be made in ample season.

Since concluding the above I have received Gleanings for March 15th, and was much pleased at seeing there Mr. Elwood's article upon the spraying of fruit-trees. At the Michigan bee-keepers' convention last January I offered to have samples of bees analyzed for the presence of poison. There should be a handful of them, whether mature bees or larvæ. To determine whether the poison came to the hive in the pollen or in the honey or in both, in cases where the larvæ are poisoned, samples of the freshly gathered honey and pollen should be inclosed. If it is possible to detect such a small quantity of arsenic as would kill a handful of bees, I think it can be done here. Having found the poison, the next step is to determine how it got there.

The strength of arsenites as recommended is generally one pound to two hundred gallons of water. Now, if each drop of these two hundred gallons contains dozens of particles of insoluble arsenic, who will say that the bee can filter them out? We know that pollen grains are found in honey and in the food of certain larvæ, probably in the latter case having entered the second stomach mentioned by Mr. Elwood, been partly digested or dissolved, then regurgitated with the larval food. Will not grains of arsenic also penetrate here and be fed to the larvæ?

Now, this arsenic can come from the trees to the hive in two ways: It may be taken in by the bee sipping the water or nectar diluted with this water containing arsenic, it which case it is very easy to see how the larvæ may be poisoned; or it may be gathered on the legs of the bee with the pollen which it takes from the blossom. In order to kill the young larva of the codling moth, the poison must lie upon the "blow," or corolla, of the embryo fruit, whence it is very liable to be gathered by the bees with the pollen or honey.

If horticulturists insist upon spraying during fruit bloom, and bees are poisoned thereby, o course laws should be made protecting the bees. I believe that fruit-men are coming to consider their own interests in the matter of spraying. Few or no entomologists recommend spraying during bloom, and fruit-men here in Michigan, with whom I have talked, are heartily in accord with the desires of bee-men on this point. Spraying before bloom may be desirable; but bees would not, I think, be injured by such spraying. It would be interesting to know what insects Prof. Lintner would combat best by spraying with arsenites during the bloom of the common fruits. With regard to the strength of the mixture of arsenites most desirable for spraying, experiments have been made at various State stations; and a gentleman who sits beside me as I write, and who has had considerable experience along this very line, says he believes there is no danger of injuring the germs of the fruit when the arsenites are of the commonly advised strength, if applied at any time. As Mr. Elwood says, there "is here room for experiment." J. H. Larrabee.

Agricultural College, Mich.

[In the above, Mr. Larrabee shows that he is the right man in the right place. In another column we publish the experiment made by the Ontario Agricultural College and Experiment Union. On page 239, J. A. Green gives some suggestions that bear directly on the line of experiments proposed above; and on page 228, Mr. Elwood suggests some practical fields for practical experimentation.]

HELEN KELLER AND TOMMY STRINGER.

THE MASSACHUSETTS SCHOOL FOR THE BLIND.

BY A. I. ROOT.

On my return home I was informed that the sum of $124.65 had been collected from the readers of Gleanings, and forwarded to Tommy Stringer. Doubtless these contributors and the readers of Gleanings in general will be pleased to learn something of the work that is being done there; and in order to give a fair glimpse of these I will make some extracts from the 16th annual report of the Perkins institution. I presume copies of this report can be obtained by writing to the Massachusetts School for the Blind, at Boston. It is a big paper-bound book of 408 pages. Besides Helen and Tommy, there is another very promising pupil from Throckmorton, Texas, named Willie Elizabeth Robin. Down south, Willie is a girl's name, as you will please remember. I have chosen her case, as it gives one an insight to the methods of working. The first extract I make gives an idea of her attainments before she came to the institution:

> Willie (nearly eight years old) was once taken to town, where she had a tooth extracted. Six months afterward the doctor who pulled it called at the house with another physician. The little girl examined the stranger first, by passing her hands over the soles of his feet, then smelling of her hands; then touching him in various places in like

manner. Finally she turned from him to the doctor whom she had met in town, and, after a similar inspection, she opened her mouth and touched with her finger the cavity left by the tooth he had extracted.

She seemed to judge the size of persons by the length of their feet; but she measured children by their height from feet to head, and chose for playmates those nearest her in size. She made known her wants by signs, and it was necessary to give her a sign but once. When she came in contact with something beyond her comprehension she would make a great effort to talk, uttering such sounds as *bah, ah, bah!* and once, about a year after her loss of hearing, she spoke the word *ma* as plainly as she used to speak it. Such was Willie Robin when her mother brought her to the kindergarten, Dec. 20, 1890.

She possesses great physical strength, and a will that is equally strong. At first, having no language with which to express her feelings, if she were urged to do something against her will, she resorted to primitive means of expression, and would strike and kick and even bite. On a few occasions, when in a passion, it has been very difficult to control her.

The following tells us of her progress just eleven days afterward:

On Dec. 31, Willie's lessons began. Three words were selected,—*fan, hat*, and *ring*,—and, provided with the corresponding objects, Miss Thayer seated herself beside her little pupil, and began work in real ernest. She gave Willie a small fan, allowed her to examine it and use it, then made the letters *f-a-n* in the child's hand. She gave her another fan, again spelling the word, and, after showing her several, of different styles, and spelling the word each time, she took a *hat* and repeated the lesson with that object. After a little while Willie grew mischievous, and hid in her apron the hand in which her teacher had spelled these words to her. In the gymnastic class she did not in the least understand the exercises, and was somewhat troublesome; but when, in the afternoon, she received her first lesson in kindergarten occupations, she did much better. With the help of her teacher she wove a mat with splints, and then began to string alternately a cube and a ball. This she liked so much that she was unwilling to leave it when the bell rang for recess.

The lessons upon these three words were repeated day after day, and she was taught to fashion the objects with paper and with clay. January 3, her teacher gave her a lump of clay, spelled *h-a-t* in her hand, and by signs indicated her wish that Willie should make one. She repeated the spelling several times, and then left the child to herself, and awaited the result. To her surprise and delight, her little pupil produced a hat. Yet she could not be sure that it was not by a happy accident that the child had hit upon the right object. She wished to test her. The day before, Willie had made first a hat and then a fan, and Miss Thayer had already seen that she was inclined to repeat things in the exact order in which they were first learned. To test her knowledge of the word, therefore, she again called for a hat, and again the little girl modeled a hat. Then her teacher spelled *f-a-n*, and Willie made this, also, after a little hesitation. She was asked to make it again, but, having made two hats, she seemed inclined to make two fans.

January 7, her teacher's diary records that she spelled the three words. January 9, she was given a lesson in the actual use of language. She dressed herself for a walk, except her hat, which her teacher had put out of her reach, so that she might ask for it in finger speech. This she did not seem inclined to do, and even sought to avoid it by pretending to be sick, by wanting water and other things; but her teacher persevered, and at last, finding that her pretenses were of no avail, she yielded, and tried to spell *hat*. The next day she was observed spelling the word in her own hand. January 12, she was taught the words *bread* and *water*, and she was again seen spelling words in her hand. In less than two weeks from her first lesson this little girl was beginning to talk to herself by the manual alphabet.

The next gives us some idea of the questions that naturally came into her little mind when she began to discover that she could make inquiries and get answers. Is it not touching?

Willie manifests so strong an inclination to *talk* that her teacher has already taught her to articulate a number of words, such as *mamma, man, mill, moo, arm, Tom*. Her voice is so natural that it is difficult to believe that she can not hear. In some way she caught the idea that we talk into people's ears; so one day she put her mouth close to the ear of her teacher, and said *mamma!* She was delighted when she found that Miss Thayer heard what she said, and put her own ear close to her teacher's mouth, that she might speak into it. She asked if Tom could hear. Her teacher told her that neither she nor Tom could hear,—that when she was a little baby she was very sick, and that made her deaf and blind. Many questions followed. She asked about Edith and Helen, Dora, Katie, and several other children who had been her companions, and was told that Helen, Edith, and Tom were blind and deaf like herself, and that Dora and Katie were blind, but they could hear. She was interested in what she was told, and probably understood it. Doubtless it is well that she has learned the fact so early, and will have ample time to become familiar with it before she is able to realize its significance.

We now come to Tommy Stringer.

On the 8th day of April Tommy was brought to the kindergarten by the nurse who had taken care of him at the hospital. He was then four years and nine months old, in good health, and physically well developed. Mentally, however, his sickness, its results and his subsequent environment had retarded his growth, and left him a pretty child, with baby face and manners. At every friendly touch he would turn with arms outstretched to encircle the neck of any stranger. He showed no preferences among persons, and would go to one as readily as to another. He walked but little, and, if left to himself, would drop upon the floor and begin to creep. He manifested a happy disposition, his face was generally lighted by a gentle, placid smile, and in his whole appearance he was a remarkably sweet and winning child. He had no signs to express his wants except those of early infancy. He would cry lustily if deprived of something he wanted, and struggle vigorously to go in the direction he wished. In creeping he usually went backward,—probably because he had learned by experience that his feet suffered less than his head in encountering obstacles. His favorite plaything was a bunch of keys, and with this he would amuse himself for a long time.

His attendant in the hospital was a night nurse, and Tommy had been accustomed to sleep much during the day and to be wakeful at night. The first efforts at the kindergarten were directed toward reversing this habit, and it was not long before he slept at the usual hours of healthy childhood. A special teacher was provided for him, and the same methods have been employed as with the other children, but as yet he has not learned the name of any object. Day after day he passively allows his fingers to be put in position to spell the name of some object which is shown to him, but he makes no attempt to form the letters for himself, and they are evidently meaningless to him. He has given up creeping, and now walks perfectly well; he examines objects with some skill, and there seems no lack of intelligence in the little fellow. As yet, however, it is only passive, and we all await with eager interest the awakening of the dormant mental powers.

The following, from our little friend Helen Keller, whom we feel somewhat acquainted with by this time, tells us in regard to Tommy's progress a little later:

South Boston, Mass., Dec. 29, 1891.

My Dear Mr. Root:—The money that you sent for Tommy came on Christmas day, and I thank you for all that has been done, through your paper, for my little friend Tommy. I saw him Christmas, and I do not believe there was a happier little boy in all the land than "baby Tom." He was sitting on the floor, in the midst of what seemed to be a wilderness of blocks, stuffed animals, steam-engines, and all sorts of toys. He appeared to like the blocks best. He has learned to weave paper very nicely, and to help himself in many ways. But he does not learn language quickly. He can spell *bread, boot*, and *mug*, and he knows that they are the names for the objects, but he does not like to ask for the things with his fingers. Teacher says he does not see the necessity for words yet. He is like a little baby, just beginning to notice things.

Please thank the kind people who have contributed to Tommy's fund, and tell them that we have eighteen hundred dollars now, almost enough to pay his expenses for three years. Surely they will all be glad to hear this good news! It will make their own lives better and happier to think that they have helped to bless and brighten a little child's life. May the New Year richly fulfill all the good wishes that my heart holds for you, and all who have helped you. Affectionately yours,

HELEN KELLER.

Now, friends, is it not true that we all feel happier for having done this little for Tommy? Is there one among us who does not feel that it has been a good investment? "He that giveth to the poor lendeth to the Lord."

A wonderful and cheering fact comes in right here. These poor deaf, dumb, and blind children have a remarkable faculty for helping *each other*. Read the following additional in regard to Willie Robin:

> Meanwhile she had made the acquaintance of Edith Thomas. From the first Willie seemed strongly attracted to her, and when, on the 13th of January, Edith went to the kindergarten for a visit of a week, the two little girls were delighted to meet, and became almost inseparable. Willie would follow Edith's every step, happy in doing just as she did; and Edith, understanding that Willie's condition was like her own, began to help in teaching her as she had herself been taught. She was told the words that Willie was trying to learn, and gently and patiently she repeated the lessons over and over to Willie, and with her help in the gymnastic exercises the new pupil began to behave much better, and tried to do as the others were doing. She evidently liked to learn from Edith, and when the time came for her little teacher to return to South Boston Willie wanted to go too.

You see, friends, poor little Willie took a new start when she found she had a comrade in her affliction; and Edith was enabled to do a kind of teaching that even the teacher could not do; that is, she, a poor blind, deaf, and dumb child could take hold of the work of educating another deaf and dumb child, and so really accomplished things that perhaps the teacher with all her faculties could not. There is a great lesson here. It is not always *angels* that are needed to help us out of our troubles. It is some child of humanity who has troubles like our own. And now we see why "God so loved the world that he gave his only begotten Son;" and this Son, in order to do his work most effectively, came down from heaven and became one of us.

> For it became him, for whom are all things, and by whom are all things, in bringing many sons unto glory, to make the captain of their salvation perfect through suffering.—HEB. 2:10.

RECENT DEVELOPMENTS.

BY E. R. ROOT.

OUR LATEST IMPROVED DOVETAILED HIVE.

What a pleasure it is to have nice accurate engravings—those that show every detail exactly as it is in the original! We recently took some photographs of the Dovetailed hive and its parts, with every thing arranged to show them up to the best advantage; and how well our engravers succeeded in reproducing the result is shown in the accompanying figures.

With the exception of one item, the separator D, no radical change has been made in the hive except what we have already illustrated in regard to the Hoffman frames and the new improved tin rabbets. These have been so universally accepted as improvements that no one has objected, even if it *were* a change. The latest change is not one that will make any serious inconvenience with hives already in use, but one that will be recognized as a move in the right direction. It is nothing more nor less than a loose wood separator, slotted out as shown in D, Figs. 1 and 2.

The whole fraternity, for the last year or two, has been gradually changing over from tin to loose wooden separators. The reasons for this are obvious. The wood costs from one-half to one-fourth as much as the tin. It is warmer—that is, wood will not conduct away the heat as will strips of metal running parallel through the heart of the cluster. Again, the surface of the tin is smooth, and bees can not readily run up and down upon it. They will therefore select the surface of the clean, nice, white cappings of the comb honey; and thus the latter, receiving from two-thirds to three-fourths of all the travel of the bees, is what is appropriately called "travel-stained." Now, by using wooden separators the bees will crawl upon the wood as readily as upon the cappings of the comb; and this must necessarily reduce to a corresponding amount the tracks of the bees on the comb honey.

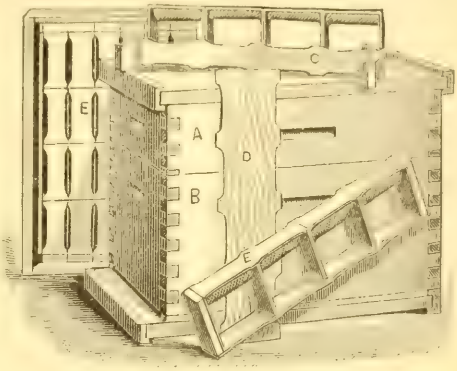


FIG. 1—THE LATEST DOVETAILED HIVE.

By increasing the width of the wood separators, we secure another and very important advantage. D, Figs. 1, 2, show a wooden separator that is 4½ inches wide. It is wide enough to cover from top to bottom the entire upright edges of the sections as well as the edges of the bottom slat C in Fig. 1. It should be remembered that ordinary separators are only 3½ inches wide, and consequently there is ¾ inch on the upright edges (and about as much of the horizontal edges of every section that is left exposed; and, worse than all, these exposed edges are the best place for the bees to chink in propolis; and the result is, a considerable in-

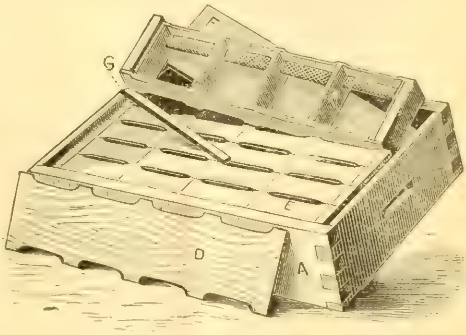

FIG. 2—DOVETAILED SUPER WITH SECTION-HOLDERS, IMPROVED WOODEN SEPARATOR, FOLLOWER AND WEDGE.

crease in the labor of scraping after the crop is removed from the hives. Our wooden separators for the Dovetailed hive, cover the entire upright edges of the sections, as well as the horizontal edges not scored out in the sections and bottom slats C, in Fig. 1, where they come in contact. With these wide separators between each row of sections, keying up closes up the interstices so that the actual scraping of the section, after the crop is finally secured, is a mere bagatelle beside the scraping of sections that have been filled in the old-style crates with narrow separators and no keying up.

Our method of keying up is illustrated very accurately in Fig. 2. G is the wedge; F, the follower. The wedge, strictly speaking, is not cuneiform, or tapering. It is simply a stick about 12 inches long, $\frac{3}{16}$ thick, $\frac{3}{8}$ wide. To key up, the follower is placed back of the last row of sections. The wedge is then inserted the narrowest way, between the super side and follower. It is then twisted so that the space between the follower and super sides is increased the widest way of the wedge, so that we now have $\frac{3}{8}$ inch instead of $\frac{3}{16}$. The end of the wedge sticking up is then turned down out of the way. The surplus arrangement is then so thoroughly keyed up that it may be turned upside down, yes, inverted, if thought advisable, when the sections are half full.

There is another feature that perhaps you may not have noticed; and that is, that, when the crop is coming in slowly, the outside rows of sections may be alternated to the center, and the center to the outside, in order to secure more even comb-building and the filling-out of sections.

As to whether this wide slotted-out wood separator is new or not, is not important; but it is important to know whether it is practicable, and whether or not it is a labor-saver in the final scraping of the sections. Such an arrangement scarcely needs to be tested to demonstrate its merits. Any bee-keeper having a practical eye will at once recognize it.

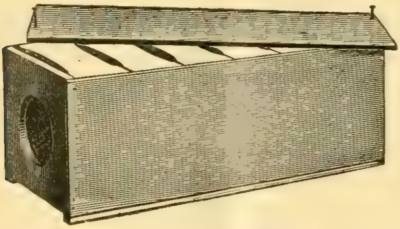

FIG. 3—D. SURPLUS CASE.

This resembles somewhat the old farmer's honey-box; and although it is now nearly relegated to the past, yet there is a demand for something on the style of the old case that will take ordinary sections. During the past eight or ten years we have filled orders, especially from California and the West, for an arrangement very similar to the D. section-case; and the fact that such a demand does not die out shows there is a legitimate call that must be supplied. When Mr. F. Danzenbaker, of Washington, D. C., was here two years ago he was very enthusiastic over a device of this sort; and while here he introduced what we have for short called the D. section-case. It contains six $1\frac{7}{8}$-inch sections, one end of which is glassed as shown. Each case is $4\frac{1}{2}$x$4\frac{1}{2}$x12 inches, outside measure. It will hold either six sections $1\frac{7}{8}$ inches wide, without separators, or seven 7-to-foot sections with small wood separators or without separators, follower and wedge. The case includes two sides, top and bottom, $\frac{1}{8}$ inch thick; and two ends, scant $\frac{3}{8}$ inch thick, and two little sticks $\frac{1}{4}$ inch thick, in lieu of T tins for the sections to rest on. Four of these section-cases will just go in a Dovetailed super, as shown in the accompanying engraving, and by the use of two supers tiering up can be practiced.

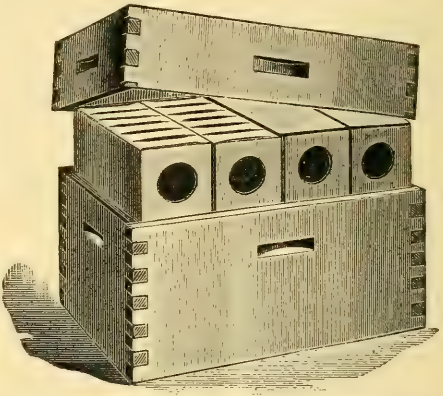

FIG. 4—SHOWING HOW THE D. SECTION-CASE IS USED ON THE DOVETAILED HIVE.

There are a good many small bee-keepers and farmers who, having only a few hives, desire to transfer the honey directly from the hives to the market. No, they don't even care to scrape the sections. They want a light little case that is both a surplus arrangement and a retailing-case—something that can be placed directly on the market among retail grocers, and that will sell for about $1.00. Of course, large honey-producers would prefer the section-holder surplus arrangement we have illustrated. But here is something that will just suit farmers. When the cases are full, if no separators are used, they can tell, without opening the hives any further than raising the super as shown in Fig. 4, just what the bees are doing. To put on the market, all they have to do is to nail on the cover and bottom. Of course, the sections may be stained somewhat with propolis; but the farmer bee-keepers do not care, because they sell honey to people whom they know—that is, right in their own vicinity.

HIGH-PRESSURE GARDENING.

BY A. I. ROOT.

I hardly need tell you there has been some pretty severe winter weather along through the middle and latter part of March. Our friends here in Medina say they saved a part of the winter expressly for me, so I need not miss it entirely, even if I was gone from the middle of November till the middle of March. In our locality it has done little harm unless to hot-beds and cold-frames not properly prepared. The fruit does not seem to be injured. Not so in the South, however. See the following, from the peach and tomato district of Mississippi:

> *Friend Root:*—The freeze struck us hard, *sure;* most of the peaches went up. Some varieties not bloomed out well, escaped. The tomato business suffered a great loss here About one-fifth were bit; but in most cases, where double beds run east and west the north side got it, even through three or four inches of straw; but no plants were lost in beds running north and south. J. W. DAY.
>
> Crystal Springs, Miss., March 21.

I suppose we may say to friend Day, that the prices will be higher in consequence, and that those who do get a crop by faithful hard labor will get a good reward for their pains. The damage to early peaches, however, is going to be a rather sad calamity.

ONION-SETS—WHAT THEY OUGHT TO BE LIKE.

The goods have been received in good order, all fully up to my expectations, except the onion-sets. They are not quite what they ought to be. No onion-set ought to be more than ½ inch in diameter, and I have sorted 1¼ pecks out of one bushel that are about one inch and over. Now, I will warrant all of these to run up a seed-stem, and perhaps a good many more; still, among the smaller lot this ought not to be so. But that is not all. They are mixed with some red onion. These red ones might be as good as the yellow, but they don't look so when put up in bundles, and I fear they will not sell so well. There is also a great difference in the two bags (I got two half-bushel bags). I would willingly give $1.00 more for the one than for the other, because it contains at least one-third more small onions than the other.

There is no question but they have been put up very carelessly; and I am sure that, if A. I. Root could only have them under his spy-glasses for one minute he would be ready to get hold of ——— Senior's shirt-sleeve and say, "Look here, old fellow, you must do better than that, or else you will ruin my reputation for sending out first-class goods only." Now, I don't want you to give me a rebate because they were not quite what they ought to have been. I only take the liberty to call your attention to it, because I think you don't know any thing about it. JULIUS JOHANNSEN.

Port Clinton, O., March 21.

Well done, friend J. Even if you have found some fault, you have given us some good pointers that I know by experience are valuable. I have become so disgusted with sets producing onions with a seed-stem, and then splitting up into two or three poor bulbs, that I have several times thought I wouldn't have any thing more to do with sets. As you are right, doubtless, we shall know how to remedy at least some of this trouble in the future. Peter Henderson and some others advertise that their sets are put through a sieve, permitting nothing to go through larger than ¾ of an inch. We notice you put it ½ inch. One thing is certain—a bushel of onion-sets under ½ inch will produce a great many more onions than the bigger ones. Those sent you were put up in my absence; but we will try to make it up to you, even if you are so good-natured you don't want any rebate. I agree with you, also, in regard to mixing red and yellow onion-sets together. Some dealers claim that it does not make any difference; but it looks to me like slipshod work. At the very high prices sets are now bringing, they certainly ought to be up to the standard you map out; and, to tell the truth, raising onion-sets is a business. To produce good ones, you want seed that is right; then you need soil that is right, and somebody to boss it who knows by experience how it should be done. There are a great many things in this world that are not as they should be; in fact, I see so many things that are wrong, almost every day of my life, that I almost think sometimes I am hard to please; but I do love to see things A No. 1; and where complaints are made in the good-natured strain in which you make them, friend J., it seems to me we ought all of us to try a little harder to do better.

STRAWBERRIES—HOW TO GET A CROP IN 60 DAYS FROM THE TIME OF PLANTING.

When Peter Henderson announced that, in his opinion, the cheapest way to grow strawberries was to have them occupy the ground only one season, there was quite a little stir about it. Since then one of the seed catalogues that advertised the Gandy strawberry sent it out under the name of the "First Season," advertising that the plants would bear a crop the same season they are put out. Well, as the Gandy fruits so very late they probably do bear a few berries. I am going to tell you of a plan whereby you can get at least a pretty good crop, and not have them occupy the ground more than 60 days. The hint of it was given me at the Inter-State Agricultural and Horticultural Convention held in Jackson, Miss. The speaker mentioned a certain field of strawberries, and gave the amount of land, and the number of quarts, and it was enormous; and he remarked that this result was obtained by selecting only such plants as had extra strong, very promising crowns; and he said, furthermore, that some of the plants, when put out, had not only blossoms but small green berries. As the ground was very rich, however, it took right hold and grew, and gave the wonderful result mentioned. Now, with the transplanting-tubes I have had good strong plants send out runners in 30 days after they were planted as I have mentioned. I have not, however, as yet tried taking up plants while in bloom; but I am making preparations to do it this season. The right kind of ground can be found just after some first crop has been removed in the spring, say spinach that has wintered over, winter onions, etc. Now, as soon as this ground can be spared, give it a heavy dressing with old well-rotted manure; work it up fine and deep, and, if possible, let the early seeds germinate. When they get near the surface, or just begin to show, rake the ground very thoroughly so as to kill every weed. This will get us a big step ahead in the matter of keeping weeds off from the crop. Now, with these transplanting-tubes select very strong, vigorous plants while in bloom. Take some of them with small green berries on if you choose. I am sure these can be moved with scarcely a setback. Take them where the plants are already too much crowded, and the bed where they are taken from will yield fully as much as before, and certainly give you larger ones. Fill the holes that are made in said bed with very rich compost. Now set the plants removed on your nicely prepared mellow ground. Keep the surface raked so as to keep weeds from starting; and if you can afford the trouble, I would keep the runners off; possibly the crop may be a little later in consequence of the transplanting. But this often gives a better price, you know. Still another thing: To avoid tramping on this soft, rich, mellow earth, I would set them in plant-beds six feet wide. In this way you can do all of the weeding and gathering without setting a foot between the plants. These plant-beds may be your ordinary hot-beds or cold-frames, where the crop has been removed. If a frost should threaten, it is an easy matter to protect them with sash or cloth. The latter can be used as friend Day uses it on tomatoes, and I do believe it will pay to raise a limited quantity of strawberries in beds covered with cloth. The danger from frost would thus be out of the question; and by having protection during cold nights they would certainly be considerably ahead of the main crop out in the field.

Terry, in the strawberry book, says that plants in the matted row should not be nearer than six inches; but in our rich plant-beds that I have spoken of I would have them about ten inches apart—this, of course, depending upon how long the bed is to be allowed to bear. If more than one year, more distance will be needed, depending upon the variety; and for such close distances the runners must be kept off, and the plant not be allowed to make more plants. In cutting runners, or even in gathering the fruit, a plank may be put across the bed from one side to the other, if found advisable.

NOTES OF TRAVEL

FROM A. I. ROOT.

Now, friends, there is a great moral here somewhere, if we can find it. At least *one* reason why we can not eat such food as other people do is because we do not have enough of the right kind of exercise. The summit of the mountain was still 1¼ miles further up; but we two did not particularly "hanker" after any more mountain climbing *that* night, "you bet." I slept in a very open bedroom, with plenty of air (and plenty of blankets), and feared I should be too stiff to move in the morning; but, to my great surprise, I wasn't stiff at all. Of course, I sat by that big cook-stove the night before until my damp clothing was perfectly dry.

In the morning we took a look at the valley below; but as the sun was not yet up to dispel the fogs and vapors of the night we seemed to be on a sort of island that pushed up through a great sea of clouds, and therefore we could only look about at the profusion of shrubbery and bushes. The picture of Camp Wilson gives you a very good idea of it. A good deal of the shrubbery that covers the mountain is the well-known manzanita, that sometimes gives quite a flow of honey in February. In fact, we found some already in bloom. It is easily recognized by the bright red wood of its branches. Very pretty rustic furniture is made from these bright-red branches. The small object on a high peak at the left of the picture (see last issue) is the observatory already mentioned.

We went to the top and back before breakfast, without a bit of trouble. At breakfast I ate with a relish several slices of fat bacon—something I never did before in my life—and, oh such lots of *other* good things! Our host had some mush made of farinose; and as they didn't have any cow up on the mountain, he told us to use with it plenty of condensed milk.

"Put on lots of butter, then lots of sugar, then lots of milk," said he: and, oh my! how delicious it was! I told him several times he was "swindled" when he made a reduction on *my* board and lodging; but he said he liked to see his guests have an appetite.

GOING DOWN THE MOUNTAIN.

Did I need my overcoat? Why, bless you, no; and yet it was so cold I found the ground frozen hard on the north side of the mountain-top, and the crust on the snow was so hard I could not get a piece loose with the heel of my boot. My sore throat, chilly right side, bowel trouble, cold in my nostrils and right ear, had all vanished in a way that seemed to me miraculous. Now, please don't think I am writing a puff in regard to the wonderful atmosphere of Wilson's Peak. Outdoor exercise and *enthusiasm* would do the same almost anywhere. Very likely the dry atmosphere of Southern California has something to do with it; and may be the soul-stirring scenery helped largely to get up the enthusiasm. While I write, a week has passed since that walk, and my appetite is still excellent, and I feel a degree of strength and vigor I think I never knew before in my life.

THE PARTY COMING TO THE RESCUE.

In many places the grade of the mountain was such that one could, if he tried hard, cut across the trail and run up the hillside so as to reach the trail at a point above. Of course, this cutting crosslots would be a great saving of time and travel; but the work is so very fatiguing, and so much harder, that most people prefer to follow the beaten track, although it takes them longer; and, in fact, few people could stand it to climb very long, straight up the sides of the mountain. In coming down the mountain, however, there are many points where the boys had "slid down" to some point in the trail below; and we made several crosscuts in this way that saved us quite a little travel. Where it was sandy and gravelly there was but little danger, even if you did fall, providing you did not tear your clothing or cut your hands and face. Friend Farr could not resist the temptation when he came to those crosscuts; and at one time he not only reached the trail below, but was under such rapid motion that he went past it and struck it still further down, saving nearly a mile of travel by what took him only a few minutes. As I had only one suit of clothing with me I did not dare to risk following him; besides, such a headlong way was more or less dangerous. In this way he reached Mrs. Root and her companions some time before I came in sight, and gravely announced that I was "used up," and he was after help. Friend Stevenson, who had brought Mrs. Root, brought along for company his niece, a schoolteacher and a young lady of rare culture and intelligence. The boys of the household also petitioned for a holiday to get acquainted with "Uncle Amos." Accordingly when freind Farr announced that I was used up they volunteered to come after me; and by dint of hard scrambling such as none but a *boy* can do, they met me coming down at a good rate along the beaten path, and soon passed the intelligence below that I was well and hearty. The first cut gives a glimpse of friend Stevenson, Mrs. Root next, then Mr. Stevenson's niece. Friend Farr brings up the rear. Your humble servant stood on the opposite side of the canyon, with the Kodak. The rocky cliffs above and below the pathway give one a very good idea of the mountain-side, and the task performed by the company who cut the trail. The next picture was taken near the foot. Mr. Stevenson and his niece come first; next Mrs. Root, then friend Farr; lastly the three boys. Two of them climbed up above a clump of bushes as you will see. Friend Stevenson has the Kodak case.

A moral lesson also comes in right here. A little of the right kind of enthusiasm will enable us to rise above temptation, in just the same way that we rise above physical weaknesses. Dear reader, can you not look back to the time when you were in a low spiritual state or plane, and when you wasted time in battling feebly against some low temptation that you now feel really ashamed of ; —in fact, that you ought to have felt ashamed of all the while? You may have wasted energy and strength in quarreling with a neighbor over some little trifle, when all your strength and energies were really needed in some wider and larger field—some place where you could have lifted humanity all around you, instead of having set a bad example to the poorest and humblest.

> They that wait upon the Lord shall renew their strength; they shall mount up with wings as eagles; they shall run, and not be weary; and they shall walk, and not faint.—Isa. 40:31.

In fact, it is with these low and earthly temptations as it is in climbing the mountains. When I once got above the plain, and looked abroad over this bright and beautiful world, I felt ashamed of being tired; and the inspiration of the grand view that opened out before me took away my weariness. When we pray for the influences of the Holy Spirit in our hearts, we should be prepared to rise above the little perplexities of every-day life. The words of my old favorite hymn come in just here:

Know, my soul, thy full salvation;
Rise o'er sin and grief and care;
Joy to find in every station
Something still to do or bear.

The last line of the hymn expresses it exactly. Instead of looking cross, and grumbling and complaining at our little trials and crosses, we want to get up high enough so we can step forward with a manly vigor; and while we draw into our lungs the beautiful invigorating air from heaven, feeling at the same time the blood forcing and tingling clear to our fingers' ends, we may also at the same time actually rejoice at the prospect of "something still to do or bear." I can not tell this, dear friends, as I should like to tell it; but I felt it that day, and I feel it yet. It is not my privilege to take you all by the hand and lead you with me along the trail up Wilson's Peak; but I exhort you to hold fast to the strong arm of the dear Savior, and let him lead you up, over and above the little trials, perplexities, and vexations of life, and along that pathway that goes ever upward as well as ever onward.

Before I start "down the mountain" let me digress again. This matter of physical health is of more importance to most of us than any thing else in the world, with *one* exception. While at Tropico friend Cole said I must meet a neighbor of his, near his apiary. When introduced, this neighbor said he knew me already, for he once had the bee-fever, took Gleanings, and read the A B C book. He gave me the following facts: His wife was nearly gone with consumption. He tried every favored locality, but she kept failing until he took her where she then was, at the foot of the mountains, near Los Angeles. The climate is dry, quite even in temperature, and no frost. By working with her husband every day, outdoors among the plants and fruits, she was really building up; and although one lung was nearly or quite gone, the other was developing to more than its usual size, so as to do the work of both. They managed so her exercise was just enough every day, and not too much.

I can not tell you *all* I saw from the top of the mountain. In fact, my story is too long already. The extreme summit seems to be on several peaks; that is, there are several that seem to be almost of a height. All are covered with heavy pine and cedar timber. One tree near the summit is marked "18 feet in circumference," and I can readily believe it true. The ocean seemed even nearer than the night before, and my companion named the different harbors all along the coast. It was all spread out before us like a map, almost from Santa Barbara to San Diego. I have inquired diligently for photographs of the valley and ocean, but am told that no camera is equal to do justice to such an immense distance. The observatory belongs to the Smithsonian Institute, and a telescope is now in process of construction for Mt. Wilson (so I am told), larger than any other in the world.

When I first took a look at the observatory from the valley below, it seemed like a miniature pint cup—a microscopic pint cup, in fact; for, after the place had been pointed out to you, you could see, glistening in the sun, the merest something made of tin. Well, when we stood beside it, it was a great circular edifice, perhaps 24 feet across and 12 feet high, covered with tin. This edifice rested on a circular track so it could be revolved by means of appropriate machinery. As the telescope rested on this structure, it could be made to cover any point in the heavens. Of course, this was a rude and temporary arrangement. The new one, with the great big telescope, is to be a very different affair, as a matter of course.

I went down with comparative ease, or at least it would have been so had I been duly prudent. We met Mrs. Root and her companions about a mile from the foot; but I was so anxious to get a particular Kodak view that I went back almost half a mile.

Did Mrs. Root get the fever as I did? This was a point I watched anxiously for. Yes, she enjoyed it almost as much I did, but she can not stand the hot sun as I can. She says, had she started quite early in the morning (say the break of day), she believes she could, under the stimulus of the wonderful scenery, have reached the shade of the trees, and from there made the whole eight miles, and enjoyed it. As it was, she went up a mile and a half, and as much more down, without *very* much fatigue. After an excellent lunch furnished by our good friend Richardson and his kind niece, we started up a canyon to see Eaton Falls. We were told it was only about a quarter of a mile up the canyon; but I think it must be a full mile of very hard walking—*much* harder than the trail up the mountain, making over 13 miles, the day after my feat of going up the mountain. I finally became so sore and stiff, that, after I sat down to rest, friend Farr would playfully lift me to my feet, and then extend his arms, as if I were a child learning to walk. For about three days the muscles of my legs were very stiff and sore; but after that I could walk three miles at a good rapid pace, without the least sign of fatigue, and now I enjoy such a foot-walk more than I ever did before.

CONVENTION NOTICES.

The next meeting of the Fayette Co. Bee-keepers' Association will be held in the City Hall at Washington C. H., O., Wednesday, Apr. 13th, 1892, commencing promptly at 10 A.M. The election of officers, in connection with an interesting program, will be the business of the day. In view of the fact that the Ohio State Bee-keepers' Association will hold its next annual meeting at Washington C. H., during the winter of 1892, we bespeak a good attendance. S. R. Morris, Sec.

Bloomingburg, O.

GLEANINGS IN BEE CULTURE
Illustrated Semi-Monthly
36 Pages 7×10
$1.00 Per Year

If any of you lack wisdom, let him ask of God, that giveth to all men liberally, and upbraideth not, and it shall be given him.—JAMES 1:5.

THE officers of the Ontario Bee-keepers' Association are as follows: President, F. A. Gemmell; Vice-president, A. Pickett; Treasurer, Martin Emigh; Secretary, W. Couse. The association is well officered, and we heartily wish it unbounded success, even though it has not seen fit to affiliate again this year with the North American.

WE regret to learn that Bro. Newman, of the *American Bee Journal*, has been quite unwell of late, as a result of the grip, and that it will be absolutely necessary for him to take a vacation of a month or six weeks. In the meantime an old employe, Mr. C. W. York, will take charge of the journal. GLEANINGS sincerely hopes that the much-needed rest will restore him to health.

SINCE our last issue, Mr. W. O. Leach, of Coldwater, Ont., the inventor of the foundation-fastener illustrated and described on page 805, Oct. 15, 1891, has demonstrated to us personally that his fastener is a success—not only in folding sections but in putting in foundation, both operations being performed with one swing of a lever. The machines, we understand, are to be made in this country by the W. T. Falconer Manufacturing Co., of Falconer, N. Y. While here, Mr. L. told us that he could fold sections and fasten starters in the same at the rate of 1500 an hour. Some time ago, when we stated that our girls, with the Daisy foundation-fastener, could put foundation in the sections at the rate of 1000 an hour, the statement was challenged as being pretty big. It seems we were not overstating, in view of Mr. Leach's achievement, because Mr. Leach can do both operations at once.

OUR honey statistics for this year have hardly got under way. In the meantime, we request every subscriber to send us a postal card, and on it answer these two questions: 1. What per cent of your bees have wintered up to date? 2. How does their condition compare with former years? It is hardly possible that we shall get a postal card from each of our ten thousand subscribers, but we look for a large number. Bee-keepers all over the land want to know (or at least ought to) how well bees have wintered, because it will have a direct bearing on the extent of the honey crop the coming season. Simply answer the questions by number, and sign your name, nothing further, and we shall know what the cards are for. Don't put this matter off but *write at once*. The answer, to be available for the next issue, should be in as soon as the 12th, and this may block out some of the more distant subscribers.

SIGN YOUR NAME, ETC.

TO-DAY we have had three letters without any signature, and two more containing drafts without any indorsement. Now, we have scolded a great deal about this already; and I have strongly emphasized the necessity of having your name printed on your stationery, envelopes, and letter-heads. But Ernest just now says that, if you don't want to do that, you can have a rubber stamp made for only 20 cts., with your name and address. If you are too busy to print it on your letter-heads and envelopes, your five-year-old boy or girl will just like the fun of doing that kind of printing for you. If you have no five-year-old boy or girl, get a brother or sister, or hire some of the neighbors' children. But please do do something, so as to abate this annoyance both to ourselves and yourself. We do not complain, mind you, because you forget once in a while. The best of people do that; but nowadays there are plenty of ways of avoiding the disastrous consequences of such forgetfulness. If you haven't done it already, go this minute and put your name and address on both your paper and envelopes; then when you come to write a letter you can write as fast as you please, and don't need to bother about the address or any thing of the sort. I think, however, you had better have that rubber stamp. A. I. R.

HOW THE BEES HAVE WINTERED AT MEDINA; THE RESULT OF OUR EXPERIMENTS WITH SEALED COVERS AND ABSORBING CUSHIONS.

ALTHOUGH the winter has been unusually severe, bees both in and out doors have wintered the best so far that we have ever known them to do. We went into winter quarters last fall with a large force of young bees, and took extra precaution that every colony should be well supplied with sealed stores, even feeding some as late as the last of November.

Of the 26 or 27 in the cellar, there are the fewest dead bees on the floor, in proportion to the number of colonies, that we have ever known. In former winters we have had to sweep up the cellar bottom two or three times, each time scooping up a good peck of bees. The paucity of dead bees on the cellar bottom this spring we attribute not only to the fact that the colonies had young bees largely, the fall previous, but to the fact that there were fewer colonies in the cellar, and consequently very much better air and better ventilation. We have always noticed this: We have lost fewer bees, in proportion, on the cellar bottom when we had only a few colonies in the cellar, than when we had a large number; consequently, as we have before stated, we are beginning to believe more and more in better ventilation in bee-cellars, and that the idea that little air or no ventilation is necessary, has worked mischief, as some bee-keepers who have tried it know to their sorrow. One prominent bee-keeper writes us that, by following this advice, or theory, or whatever it may be called, that too much ventilation in the cellar is detrimental on unnecessary, he lost several hundred dollars. P. H. Elwood, who winters a little over one thousand colonies in one cellar, believes in plenty of ventilation of the sub-earth sort; and when bees are noisy he lets them have more air.

So much for cellar wintering. As to our colonies outdoors, we have so far at this date, March 26, not lost a single one out of a total of about 150. With the exception of two weak ones which we united, the rest were all strong and showed no signs of dysentery, and all seemed to be wintering about alike, and it did not seem to make very much difference whether they had absorbing cushions or sealed covers. If any thing, the difference is a little in favor of the sealed-cover hives, judging from those having glass tops. Another fact should be observed—that the sealed-cover colonies have had only about two inches of chaff or planer shavings, while the colonies with absorbing cushions have had anywhere from six to ten inches of chaff.

There is also another reason why our colonies are wintering so well. We have had continuously cold weather, with scarcely a day for flight, since about the middle of December. March, instead of coming in like a lamb, as it usually does with us, and allowing brood-rearing to get well under way, and finally going out like a lion, chilling the brood and giving the bees a bad setback, *this year* came in like a lion; and from present appearances it is going out like a lamb. The result is, we discover no traces of brood-rearing, and colonies have not been obliged, therefore, to disperse their strength and heat by trying to cover brood. Our March weather has been most favorable in that it was extremely cold—hanging around the zero-mark.

AGAINST ARTIFICIAL SUBSTITUTES FOR POLLEN, SUCH AS MEAL, FOR STIMULATING BROOD-REARING.

Our apiarist asked us whether he should put out any artificial substitutes for pollen, such as meal. We replied that we should rather not, and he readily agreed. It is desirable to have early brood-rearing for the early honey crop, but it is bad to have it get well under way *too* early in the season, and then have it killed by a cold snap. With our present light we do not care to encourage brood-rearing before the advent of settled warm weather, and therefore pollen from natural sources, such as soft maples, comes in just about the right time.

Times are changing. Two or three years ago self-spacing frames were not considered practical, and the reversing features of the latest honey-extractors were regarded as just so much surplus machinery. But bee-keepers are thinking differently now. Honey is being produced on larger scales, and better and more rapidly operated appliances are demanded; and these things come of necessity. While we welcome these improvements we should be careful not to chase after every "new fad."

The following, from the *American Bee Journal*, gives just the information that many are seeking:

> I see in the *Home Journal*, page 85, that space at the World's Fair must be applied for on or before July 1, 1892. I would suggest that you give plain directions as to whom to apply, and the expense of space, in the *American Bee Journal* and *Home Journal*, and oblige your MANY FRIENDS.

The editor replies:

> Apply to Mr. W. I. Buchanan, Rand-McNally Building, Chicago, Ill. There is no charge for space. Until a superintendent is appointed for the Apiarian Department, nothing definite can be arranged.

ADULTERATED EXTRACTED HONEY, AGAIN.

The adulterated-honey matter is not dropped by any manner of means. We are still collecting evidence, and an attorney's advice has been sought in one of the neighboring cities. When the right time comes we propose to make a move. We may not be able to accomplish much, but it will not be from lack of effort on our part if we do fail. In the meantime it is to the interest of every honest bee-keeper to see that adulteration of honey is stopped right in his own vicinity. The State and local bee-keepers' societies are the proper ones to make the fight. What are our societies good for if they can't do something of this kind? But for goodness' sake don't go and make a great furor and false alarm until you are morally certain that honey *is* adulterated in your locality.

Many of the mixers will be "scared" if you only let them know in a quiet way, that, as an organized body of bee-keepers, you propose to make an *effort* against them. If you can scare them into putting only pure honey on the market, you have accomplished your object without further warfare. This is no idle talk, for one firm with whom we have had correspondence relative to their adulterating honey, and what we proposed to do—well, we imagine are just a "leetle scared." The fact is, they know the law in their State is pretty strict, and that we mean business.

THE EDISON PHONOGRAPH.

It is really true, dear friends, that one of these wonderful machines is already in our office. In fact, I am just now dictating this, my first effort, with the machine. Well did our good friend Falconer say that it seemed like sitting down to one of the buzz-saws and talking to the machine It is noontime in the factory, and the hands have just been round the instrument listening to some beautiful pieces of music which were kindly sent with the machine to us. When the announcement of the piece is made it really seems as if we could be with the speaker as he stood before a sea of faces in some vast audience. He raises his voice, and, with the inspiration natural under such circumstances, he introduces the melody. Then we can see the band of musicians, each one taking up his instrument to do his level best, and here we have it away back in Medina, with a crowd of listeners all around us listening to these soul-inspiring strains. One of the pieces is a whistling piece, and the happy melody of the whistler is so infectious as to get hold of each one of us. Some of the old, staid, gray-headed ones, almost seemed inclined to begin to swing their hats, and skip about. By the aid of a large black horn the sound of the voices and instruments are plain enough so they may be heard all over the room. In fact, while we sit at our tasks several feet off from the instrument we can hear the melody of the pieces. I have so far occupied about half of one of the cylinders. After it is talked all over (or *written* all over, whichever you would call it) it can be turned off by an appropriate machine, and then we can write it over again. Each cylinder is capable of being turned off from 50 to 60 times. To hear familiar voices uttered so lifelike and plainly from the instrument seems something even more wonderful than any of the tales of the Arabian Nights. But here it *is* a startling and tangible reality; and one holds his breath, as it were, while he stops to think what is coming next. Who knows but the time may be near at hand when the editor of GLEANINGS will be able to speak in his own natural voice to his 10,000 readers? May God help us to make good use of the opportunities that lie about us during this 19th century.

As I brush the dust from the cylinder and notice the indentations produced by my voice, it seems absolutely wonderful that human ingenuity has been enabled to make use of these microscopic indentations; and yet it is indeed true; for when, by a little modification of the instrument, it is made to speak back to me the words I have been speaking, they are even plainer than I ordinarily utter them; and even the sound of my breathing has been faithfully recorded.

The great value of the instrument in a business point of view is this: The business man may at night, whenever he has leisure, or whenever he *feels* like it, talk his messages that are to be made known to the world, to the machine; and after this, when it may be convenient an operator, not necessarily a shorthand writer or one particularly skilled, may take the machine and simply transcribe what is spoken to him as plainly as his employer would speak to him if he were constantly by his side. Nay, he can make it speak it over and over as many times as he wishes, and he can then, at his own leisure, write up the letters. As the machine has sinews of steel and brains of lightning it is not expected that it will get sick; but there it stands at its post, day and night, ready to take down messages whenever its owner shall feel like giving them. The moter power that runs the machine is one of the noted *storage batteries*; and what a wonderful thing is this storage battery! Ours, although it cost only $15.00, will run the machine 30 hours; and when it is run down (or emptied) it can then be replenished by our dynamo, and it is ready for 30 hours more. The world scarcely yet dreams what is forthcoming from storage batteries. I am told already that an electric railway car is being run in the city of Cleveland by aid of the storage battery. Thus these overhead wires that have been making so much trouble, and have been the cause of the loss of lives, are to be dispensed with. Our storage battery weighs 25 lbs., and occupies comparatively little space. When the machine is to be used we first start the electro-motor run by the storage battery; then when the operator is ready to speak, he simply turns the lever that sets the recording point to work. A. I. R.

TOBACCO COLUMN.

CONDITIONS UNDER WHICH WE GIVE SMOKERS TO PERSONS WHO STOP USING TOBACCO.

First, the candidate must be one of those who have given up tobacco in consequence of what he has seen and read in this department. Second, he promises to pay for the smoker should he ever resume the use of tobacco in any form, after receiving the smoker. Third, he must be a subscriber to GLEANINGS. Any subscriber may, however, have smokers sent to neighbors or personal acquaintances whom he has labored with on the matter of tobacco-using, providing he give us his pledge that, if the one who receives the smoker ever uses tobacco again, he (the subscriber) will pay for the smoker. The one who receives the smoker in this case need not be a subscriber to GLEANINGS, though we greatly prefer that he be one, because we think he would be strengthened by reading the testimonials from time to time in regard to this matter. The full name and address of every one who makes the promise must be furnished for publication

If you wish to add one more to your tobacco list, you may send me a smoker and I will live up to the requirements. R. M. LEWIS.
Omaha, Neb., Oct. 17.

Please send a smoker to H. B. Robinson He says if you do he will not use any more tobacco; if he does I will pay for the smoker.
Tracy Creek, N. Y. MRS H. B. ROBINSON.

Please forward to my address one smoker for Geo. W. Crist, who has quit the use of tobacco, partly through the influence of GLEANINGS. If he should relapse I will see that you are paid for the smoker. JOHN NEWSOME.
Woodburn, Ia., Oct. 26.

Since I have subscribed for GLEANINGS I have resolved to quit the use of tobacco for ever. Please send me a smoker. I will pay for it if I use it again. L. C. WORTH.
Loyd, Wis., Jan. 29.

I have another convert to report. Please send a smoker to W. H. Hughes, Sonoraville, Ga. If I ever know him to use the weed again I will pay for the smoker. R. W. STEWART.
Sonoraville, Ga., Jan. 16.

Please send a smoker to R. L. Benford, Hampden Sidney, Virginia. He stopped the use of tobacco two months ago, after using it ten years, and if he ever uses it again I will pay for the smoker. LUCY E. MARTIN.
Hampden Sidney, Va., Oct. 12.

I read the Tobacco Column and your promise to give a smoker to all who would quit using tobacco. I never smoked a pipe of tobacco in my life, but I smoke my bees with a cigar. I often make myself sick. I don't know how the poor bees feel; but I give you my pledge to quit using tobacco in all its forms, with the Lord's help, or I will pay for the smoker.
Streator, Ill., Oct. 7. THOS. B. FERGUSON.

Send Mr. Matthew Strickland, of this place, one smoker. He has quit the use of tobacco for ever, and promises to pay for the smoker if he ever uses tobacco again. W. B. ENOCHS.
Emporia, Miss., Feb. 20.

Mr. L. F. Clark, of this place, has used tobacco for over thirty years. Since he has taken GLEANINGS he has quit; and if you will send him a smoker he will pay for it if he ever commences again. F. J. FARR.
Acton, Cal., Sept. 11.

You will find inclosed 70 cts. for payment on the smoker you sent me for my friend Robert Jones as a reward for his quitting the use of tobacco. I am very sorry he has begun the use of tobacco again. He paid me for the smoker, and requested me to pay you for the same.
Morgan, Ky., Dec. 26. HENRY C. CLEMONS.

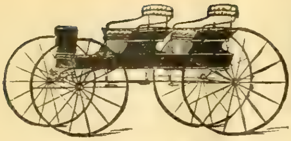
I have this day received a promise from Mr. Ed. Germane that he will discontinue the use of tobacco from this date. This promise is secured through the influence of GLEANINGS, and by my persuasion. You will please send a smoker to his address, which is Terre Haute, Ind. In case this promise is broken I am security for payment of smoker. W. SHIELDS.
Terre Haute, Ind., Sept. 29.

I have been persuaded by what I have read in GLEANINGS, to quit the use of tobacco. Please send me a smoker; and if I ever use tobacco again I will pay for the smoker. Please send a smoker also to Charles Hodges, who has, through the influence of reading your Tobacco Column and Home Papers, in my GLEANINGS, concluded to quit the use of tobacco. Please send him a smoker; and if he ever uses the weed again I will pay for the smoker.
Annin Creek, Pa., Oct. 10. G. F. TUBBS, JR.

I chewed tobacco from a boy until I was some 25 or 30, and quit, firmly convinced it was closely related to the whisky habit. I have smoked for over 25 years. One year ago last January I firmly decided never to use the weed again, and have not touched it. To many tobacco friends I would pleadingly say: Abandon the soul-destroying weed, and the money spent for the poisonous luxury invest in literature for the family—our boys, our girls, and our neighbors. If I am entitled to a smoker, please send one to my address. WM. H. SWIGART.
Dixon, Ill., Feb. 25.

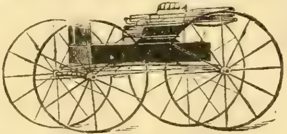
Last May we took a boy to raise. He is only 13 years old, and was in the habit of chewing obacco, and had been for four or five years. We shamed him about it, and I told him that, if he would quit its use, Mr. Root would give him a smoker, and that we would give him a colony of bees, also a nice suit of clothes at Christmas. At first he thought he could not do without tobacco; and his mother, a widow, told me I would have to let him use it, as she thought he could not quit. Finally, in August last, he made up his mind to quit, and has not tasted it since, so I gave him the bees and a suit of clothes; and now as he saw me writing to you he reminded me about the smoker. If you think he is entitled to it you can send it. His name is Daniel Bissell. If he uses tobacco again I will see that the smoker is paid for. R. J. MATHEWS.
Rosedale, Miss., Feb. 15.

ALLIANCE, GRANGE, LEAGUE



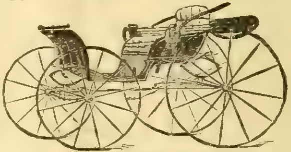
"A" Grade $40.

F.M.B.A. Members and thousands of other good men and true, patronized us so liberally last year that we were compelled to buy, build and increase our facilities until now we now have one of the **LARGEST CARRIAGE and HARNESS FACTORIES IN THE WORLD.** The Alliance Factory runs when others shut down or break up.



"A" Grade $46.

Send for our handsome, illustrated Catalogue, showing over 100 different styles of Vehicles and Harness, and you will understand why all this phenomenal success and immense business. We actually give more for less money than any Buggy or Harness factory in the world. All goods hand made and warranted for years. Get our prices and compare them with your dealers.



"A" Grade $72.50.

ALLIANCE CARRIAGE CO. CINCINNATI, O.
North Court St., opp. the Court House.

SOLID GOLD.

He sat in his bee-yard at noonday,
He was lonely, glum, and sad;
The bees were buzzing about him,
And he was swearing mad.
Not an ounce of surplus honey,
Not a dime in his pocket for bread,
But the black bees kept on buzzing
About the old man's head.
At last, in despair he shouted,
"I would that I were dead!"
Then came the sound of sweet music,
He stood as in a trance,
The birds sang,
"*Buy the W. V. M. ITALIANS*,
And then of joy you will dance."

Rates: Virgin queens, 40c; untested, $1.00; tested, $2.00; select, $3.00; tested breeding queens, $4.00. Untested queens, ready May 20.

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All advertisements intended for this department must not exceed five lines, and you must SAY you want your adv't in this department, or we will not be responsible for errors. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. This department is intended only for bona-fide exchanges. Exchanges for cash or for price lists, or notices offering articles for sale, can not be inserted under this head. For such our regular rates of 20 cts. a line will be charged, and they will be put with the regular advertisements. We can not be responsible for dissatisfaction arising from these "swaps."

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they wish to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough in these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I have 50 good hybrids and black queens for sale at 25c each, ready for immediate delivery.
6-7d W. H. HEASTMAN, Citra, Marion Co., Florida.

Mismated queens, 35c each, three to one address for $1.00. W. C. GATHRIGHT,
Toccopola, Pontotoc Co., Miss.

A fine mismated five-banded, golden Italian queen, nearly solid yellow; bees, black to four-banded, 40c. Also a few of the same strain that show a few bees with only 2 bands (none less) they are evidently mated with hybrid drones, so they go at 60c. Stamps, ones and twos. S. F. & I. TREGO, Swedona, Ill.

40 young mismated and hybrid queens from an out-apiary will be sold for 35c each after April 20th.

REMEMBER

THAT IN THE

Pecos Valley

The Fruit Belt

OF

New Mexico,

FARMERS COINED MONEY

during the Summer of '91, and will do so every year.

For instance :

Thomas Stokes raised 11 tons of sorghum (hay) on less than two acres of new ground, which product he sold at $15 a ton—**cash yield over $83 an acre.**

Julian Smith sold **over $300 worth** of garden products **from half an acre** of ground.

W. W. Paul raised 211 bushels of oats on 2 1-5 acres of ground, sold at 70 cents a bushel—**cash yield $67 an acre.**

John W. Poe cut 600 tons of alfalfa from 110 acres; value $15 a ton, $9,000. **Cash yield per acre, $80.**

L. W. Holt raised 11¼ tons of sorghum on 1½ acres, and 450 tons of alfalfa on 90 acres. The alfalfa sold at $15 a ton—**cash yield $112.50 an acre.**

We can give you plenty of similar examples when you come here.

Send for illustrated pamphlets, giving full particulars.

Pecos Irrigation and Improvement Co.,
EDDY, NEW MEXICO.

Burdsal Apiary and Supply Co., Lebanon, O.
Leahy Manufacturing Co., Higginsville, Mo.
C. E. Lukens, 19 North Second St., Philadelphia.

SPECIAL NOTICES.

CONCORD GRAPEVINES, FOR SHADING BEE-HIVES.

Strong, well-rooted, three-year-old plants, 10 cents each; 10 for 85c; $7.50 per 100.

DECLINE IN POTATOES.

Until further notice we will furnish Early Puritan potatoes, Lee's Favorite, or Monroe Seedling, at 75 cts. per bushel, or $2.00 per barrel of 11 pecks.

SLICED SLOTTED SEPARATORS.

You will notice these slotted separators, which were shown in our last issue, are priced in our March 1st catalogue at 60 cts. per 100; $5.00 per 1000. We have a few from one lot we made that molded a little in drying, which we will sell at half price. There are only two or three thousand of them.

COMB FOUNDATION.

We should be pleased to send free samples of our foundation on application to prove that we are not behind any of our competitors in the quality of the goods we send out, both in color and workmanship. Competent judges have acknowledged ours equal to Dadant's, which is the standard.

SAWED SEPARATORS.

The ordinary sliced wood separators have a tendency to curl considerably, and this is about the only real objection to them. As some prefer not to use them on account of this, we have been making sawed wood separators, about 14 to the inch, very straight and smooth, 3½ x 17 to 18 inches long, at 60 cts. per 100; $5.00 per 1000. We have not made any sawed slotted separators.

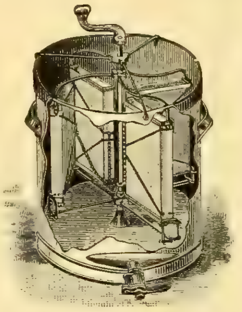
ALSIKE CLOVER SEED.

It is not too late to sow alsike, and we still have a good supply of nice clean seed. As the season is getting late and the market a little easier, we will make the price for the next 30 days as follows: 2 bushels, $18.00; 1 bushel, $9.50; ½ bushel, $4.90; 1 peck, $2.50; 1 lb., 20 cts.; by mail, 30 cts.

BUSINESS AT THIS DATE.

We have our usual supply of orders for this season of the year, and, if any thing, they are larger. As we were prepared with a stock of all standard goods to draw on in addition to what we make from day to day, we are able to rush the goods off within a few days after receiving the orders. The invoice you receive from us shows the record on the upper left-hand corner, telling just how long the order is in our hands before being shipped. We aim to make the time covered by this record as short as possible. We hope to serve you with the same promptness through the season that we have been able to do so far.

STANLEY AUTOMATIC REVERSING HONEY-EXTRACTOR.



As announced in last number of Gleanings, we have leased from G. W. Stanley the right to make his automatic extractor, and we bought from E. R. Newcomb his stock of materials and machines unsold. This stock consists of about twenty-five machines, two and four frame. To work it off quick, and give us a chance to put out machines of our own make, we offer these machines as long as they last, at one-fourth off old prices. We will sell the two-frame machines as they are for $9.00; the 4-frame for $15.00. They are crated ready for shipment, with crank direct on the center-shaft. We will attach our new horizontal gear, as shown on page 14 of our catalogue, for $3.00 each extra.

THE PLANT BUSINESS AT THIS DATE.

During the fore part of April we had several days of very nice weather—so much so that the gardener, and even the plants too, were about to be deluded into thinking that frost and snow for the season were at an end. Since then, however, the weather has been cold, and the ground has been frozen up so it would almost bear up a horse in the forenoon. Now, we are not complaining at this sort of thing, mind you, for it has been the means of keeping the fruit back so there is great probability that it will escape uninjured. But at the same time the weather has not been favorable for sending out strawberries and other kinds of plants. While I write, the frost has let up, but it is snowing. Just as soon as this is over we expect to rush off every thing promptly. Even the cold-frame cabbages that have been frozen again and again for the last half of the winter could hardly stand the cutting north winds. What few we had in the open ground were pretty much used up except the small central leaf. The prospect is, therefore, that the one who had his stuff well protected, or had good strong plants that could withstand the freezing and cutting winds, will get a big price for what he has to sell.

TWO NEW BOOKS—HENS AND "RATS."

The *Rural New-Yorker* sends us two very pretty little industrial manuals. The first is entitled "The Business Hen." It was written by H. W. Collingwood, managing editor of the *Rural New-Yorker*, with special articles by more than a dozen of the prominent authorities on poultry. The price is 75 cts., in neat cloth binding; paper, 40 cts. The other book is on "rats,"—how to rid buildings and farms of rats and other pests of like character. The book is by "Picket." It is written in one of his happiest veins, and it is very interesting reading aside from its valuable teachings. In fact, it seems to cover about every plan known for destroying, driving away, or fencing out these fearful pests. I have often said it is a disgrace to any neighborhood or any community to have rats around doing damage, and I say so still. The rat-book is only 20 cts. For either of them send to the Rural Publishing Co., New York; or, if more convenient, you can get the "rat-book" of us for 18 cts.; postpaid by mail, 20.

ONE-PIECE SECTIONS.

We are now making one-piece sections at the rate of a million a month. In the five months from Aug. 1st to Jan. 1st we made about one and three-quarter millions; in January and February, one and one-quarter millions; and since the first of March we have been turning them out at the rate of a million a month. We now have in stock about one and a half millions of all widths of the $4\frac{1}{4}$ inch section from $1\frac{1}{2}$ inches up to 2 inches. We have also enough dry lumber in our yard to make about three million more. By the time this is worked up the lumber we have contracted, cut the past winter, will be ready to begin on, and this will make six or eight million more. The quality of the sections is superior to any we ever sent out in former years, and, we believe, equal to any made, and superior to most makes. We contracted to supply one large dealer at a higher price than he was offered other good sections for, because he decided that ours would please his customers enough better to pay the difference in price. We are also making lower prices in large lots to dealers than we have been able to do heretofore. We mention all these things to show you how well prepared we are to serve you. Last year, and the year before, our supply of lumber suitable for sections was insufficient, and, as a consequence, to fill orders at all we were compelled to send out some that were rather inferior for first grade. To many of our friends who received these goods we have allowed a rebate, and to others who mentioned it in their orders we have sent an extra supply of the choice sections we are now turning out. If there are any who have not yet had satisfaction we want to hear from you so that we may have an opportunity to give you satisfaction, and to give you sections that can not be surpassed by any manufacturer.

Kind Words From Our Customers.

I don't see how one who has had a taste of GLEANINGS can expect to get a better feast. It's every thing to me. Gardening and Home talk and all are so social it seems as if I had you by the arm looking over my fruits, etc. Long may you live to cheer us, especially by the welcome address of the word "friend." God bless you. E. P. CHURCHILL.

Hallowell, Maine.

I just unpacked the goods I received from you, and am more than pleased with the same. They arrived in the best possible condition, and give good satisfaction for the future. The workmanship of the hives is the finest I ever saw. My neighbors say they never saw wood so well made and accurate, as it is worked by automatic machinery. Your manner of packing is excellent, and answers well for long distances. The lot of medium foundation is first quality in all respects. The freight on these goods was very low. The duty was rather high. As long as I receive goods like these you can reckon on me as a customer, though it is as far as 600 miles from you. JOS. BEAUDRY.

St. Marc, Can., Feb. 7.

PROMPT FILLING OF ORDERS; THE KIND OF ADVERTISING THAT PAYS.

I got two queens from you last summer, and they were fine ones. They were safely introduced. I like the Benton cage. I have bought quite a good many queens, but yours came the quickest of any I have had yet. I did not have to go to the office five or six times, as I have had to do before, for I had them in a few days. I shall know where to get them after this. FRANCIS ORTT.

Darling Road, O. N. T.

[Knowing, as we do, that, when a customer orders a queen, he wants it at once or his colony will suffer, we bend every energy to send all queens by return mail. How this is appreciated, many letters at hand testify.]

HONEY COLUMN.

CITY MARKETS.

MINNEAPOLIS.—*Honey.*—The honey-market is declining considerably. The demand is dropping off, and fancy white honey is now being sold for 16c; choice, 14; dark, 8@12, according to the quality.

Mar. 28. J. A. SHEA & CO.,
14 & 16 Hennepin Ave., Minneapolis, Minn.

ALBANY.—*Honey.*—There is quite a large stock of comb honey on the market yet, and but very little demand. Extracted about all cleared out. There is no established price on comb honey; it sells at 6@10. CHAS. MCCULLOCH & CO.,
Apr. 8. Albany, N. Y.

CINCINNATI.—*Honey.*—There is a slow demand for comb honey, with a good supply on the market. Prices are nominal, at 12@15 in the jobbing way. *Beeswax* is in good demand, at 25@27, for good to choice yellow on arrival. CHAS. F. MUTH,
Apr. 11. Cincinnati, Ohio.

CHICAGO.—*Honey.* Honey-market now quiet. Sales of comb made in a small way; there is very little fine comb on sale, with prices of 15c for best, to 16 for a fancy article. Extracted in steady demand, with stock very light. *Beeswax*, 27 for yellow.

R. A. BURNETT,
Apr. 7. 161 So. Water St., Chicago, Ill.

BOSTON.—*Honey.*—We quote you our honey-market as being well supplied, fair demand. One-pound combs selling at 13@15; no 2-lbs. on hand. Extracted honey, 7@7½. *Beeswax*, none.

Apr. 8. BLAKE & RIPLEY,
Boston, Mass.

NEW YORK.—*Honey.*—Not much change in honey-market since last issue. There is a little demand for fancy 1-lb. sections, only fancy; but the market seems to be pretty well cleaned up of the above grade of goods. We quote the following: Fancy 1-lb., 12; 2-lb., 11; fair, 1-lb., 9; 2-lb., 8; buckwheat, 1-lb., 8; 2-lb., 7. Extracted, 6½@7, for clover; 5@5½ for buckwheat; southern, from 65@75c per gal. *Beeswax*, 27@29.

Apr. 8. CHAS. ISRAEL & BRO.,
110 Hudson St., New York.

KANSAS CITY.—*Honey.*—Demand poor, with a large supply of comb. We quote: Comb, 1-lb., fancy, 12@13; dark, 8@9. Extracted, white, 7; dark, 5@6. *Beeswax*, none on the market.

Mar. 21. HAMBLIN & BEARSS,
514 Walnut St., Kansas City, Mo.

SAINT LOUIS. *Honey.* Inquiries for strained were frequent, and business more satisfactory. No quotable change in values. *Beeswax*, prime, 27½.

Apr. 8. D. G. TUTT GRO. CO.,
St. Louis, Mo.

KANSAS CITY. *Honey.* The demand for both comb and extracted continues light. We quote:
1-lb. comb, No. 1, white, 13@14; No. 2, white, 10@12; No. 1, amber, 12@13; No. 2, amber, 8@10. Extracted, white, 6@7; amber and dark, 5@6. *Beeswax*, 22@26.

Apr. 9. CLEMONS, MASON & CO.,
Kansas City, Mo.

DETROIT.—*Honey.*—Comb honey is dull and selling very slowly at 11@12½. Not much on the market. Extracted, 7@8. *Beeswax*, in fair demand, 27@28.

Apr. 8. M. H. HUNT,
Bell Branch, Mich.

FOR SALE OR EXCHANGE.

One 10-in. Root's mill for brood-foundation, and 1 6-in. mill for thin foundation in good order, and at a bargain, as we do not keep bees now. 7-12db

My 654 Colonies of Italians

Are wintering well, and, as usual, I will sell a limited number of them to reduce stock to the required number. Each hive shipped to my customers will contain a full prosperous colony of Italian bees, with a last year's tested queen, on eight Hoffman frames of brood and honey. As my main object in handling bees is honey, we raise all our queens in full colonies from cells built under the swarming impulse, using the choicest and most profitable stock to breed from.

Safe arrival guaranteed in May and first half of June. For terms please address

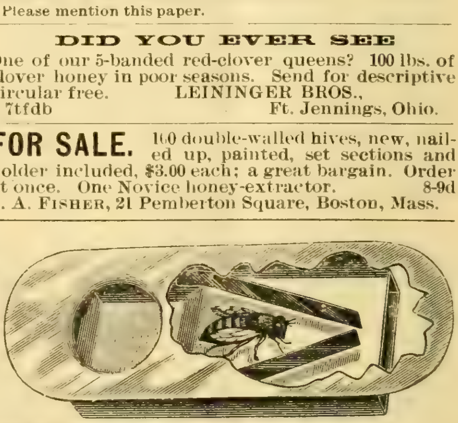
One of our 5-banded red-clover queens? 100 lbs. of clover honey in poor seasons. Send for descriptive circular free. LEININGER BROS.,
7tfdb Ft. Jennings, Ohio.

FOR SALE. 100 double-walled hives, new, nailed up, painted, set sections and holder included, $3.00 each; a great bargain. Order at once. One Novice honey-extractor. 8-9d
S. A. FISHER, 21 Pemberton Square, Boston, Mass.

Porter's Spring Bee-Escape.



We guarantee it to be the best escape known, and far superior to all others. If, on trial of from one to a dozen, you do not find them so, or if they do not prove satisfactory in every way, return them by mail within 90 days after receipt, and we will refund your money.

PRICES:—Each, by mail, postpaid, with full directions, 20c; per dozen, $2.25. Send for circular and testimonials. Supply dealers, send for wholesale prices.

10tfdb *R. & E. C. PORTER, LEWISTOWN, ILL.*

Vol. XX. APRIL 15, 1892. No. 8.

STRAY STRAWS

FROM DR. C. C. MILLER.

Bees come out of cellar to-day. April 7.

How's electricity? Is it a success for wiring?

Onion - plants by mail! Well, I never! What next?

D. A. Jones's name is again at the masthead of the *C. B. J.* Long may it stay there!

I got a letter from Medina written by a phonograph. I could read it as easy as any letter.

Slang is something I don't use very often; but you will pardon me for saying that the Daisy foundation-fastener is a *daisy*.

California is a great place for all grains and fruits; and if that on page 242 is a fair sample, they raise the best quality of "straw" there.

The *American Bee-keeper* is doing missionary work by sending free copies of an article from *Harper's Weekly* on "better country roads." A good move.

Prevention of after-swarms is thus secured by T. Heiss (*A. B. J.*): Next day after swarming, run in a virgin queen between the combs and she'll destroy all cells.

Now that Larrabee has got out of his shell, let's be sociable with him. I think he told me that only one man had responded to his request for subjects proper for experiment.

Rev. W. F. Clarke has reduced "the bad five" to the "big four," but he doesn't say which one of the five has been expelled. He talks real cross in the *C. B. J.* about the other four.

You want a postal right away, friend Root, telling how many colonies have wintered. How am I to know without stirring them all up down cellar? They are all quiet there this 6th of April.

Dadant, referring to Gerstung's theory of the queen having periodic intermissions of laying, says that, in constant examinations when engaged in queen-rearing, he has never observed any thing of the kind.

Old sections that are so dry as to break when being made up I have always thought were best treated by being left down cellar for some time. This spring I had to give up, that hot-water treatment is better.

Onion-sets, friend Root says, need right seed, right soil, and all that sort of thing. When I was a boy they just planted them so thick that they couldn't grow big and that was all there was to it. They were good sets, weren't they?

That's a good article by J. A. Buchanan, page 232; but isn't he off when he thinks he sells more honey on account of the adulterated stuff? And why should he wish "to bring to justice these robbers," the adulterators, if they are helping his sales?

I always thought Elwood knew a good deal, but that article on p. 228 shows he knows more than I thought he did. His head is especially level when he says there will never be satisfactory work done in the government apicultural department till it is independent, and in charge of a bee-keeper.

The *American Bee-keeper* sent inquiries to 5000 bee-keepers, asking the number and style of hives. I should have said that one hive in twenty might have been of box persuasion; but they make the startling statement, "We find that a very large majority of the hives used are of the old box style."

Friend Root, if you will look a little closer you'll see that Dr. Kellogg is all right on p. 235. He says that the bee rubs pollen off the flowers, "and carries it home with *him*." You see it's the he-bees he is talking about. Now, you just eat some of the pollen a drone carries home with him, and see if it doesn't poison you.

Too bad my bees can't have a chance to work on the soft maples which are in full bloom since April 1; but it's too windy, cloudy, and rainy to set them out, although the thermometer has been up to 72°. Besides, it's not certain spring is here to stay, so the bees will just have to stay where they are, and roar if they want to.

Those big bee-men of New York are all right and sensible, Mr. California-Man, not to report their big crops. In reply to your other question, the reasons applicable to bee-men *are* used by others. A man who has horses, cows, or any other live stock except bees, secures control of the territory on which they feed, and why shouldn't bee-men?

To cure sections that are so dry as to break when put together, leave them in the box and pour boiling water so it will run down through the whole box. Don't have your tea-kettle too full, and pour in a stream about as large as a goose quill, moving slowly along the three lines of joints where they are to be broken. Don't get any water on the dovetails.

I may say to friend Greiner, that, while I believe young bees as a rule do not work in the field till 16 days old, I *know* that the rule may be broken by circumstances. I made the same experiment as Vogel, using only sealed and hatching brood, and at five days of age workers were carrying in pollen. Now, if tense pressure made such a difference in this case, is it not possible that sufficient pressure often occurs to vary the rule more or less?

The *American Bee-keeper* gave due notice that its name was not to be squeezed down into the compass of three initials; but it takes so much ink to write the whole of it that the editor has begun to drop off the first eight letters himself, and he uses merely initials for the names of other bee-journals. Say, *A. B. K.*, you'll not be so very mad if I initial you after this, will you?

April 4 my bees were howling down cellar, with the thermometer 72° outdoors. Opened up doors at dark, and let a strong wind blow in all night. Bees quiet as mice in the morning, with thermometer in cellar at 50°, and stayed so, although door was open all day, letting in full daylight. Don't tell me bees need no ventilation in cellar. Mind you, they had been confined five months.

Those who are anxious for fear the cells of old combs may become so diminished in diameter that the young bees hatched therefrom may not be of normal size, should remember that the chief part of the deposits left from cocoons are at the bottom of the cell; and as fast as these are left, the cell-walls are lengthened outwardly, from which it will be seen that, at the mouth of the cell, the diameter must always be the same.

THE POSSIBLE AND ACTUAL COST OF COMB HONEY.

P. H. ELWOOD CRITICISES TAYLOR'S AND HILTON'S ESTIMATES, AND DEFENDS DOOLITTLE'S.

Langstroth says it is an easy matter to make calculations on paper almost as flattering as an imaginary tour to the gold-mines of Australia or California. The following calculation of *possible* profits from bee culture, taken from Lydserff's Treatise on Bees, published in England in 1792, is a perfect gem of its kind:

> Suppose a swarm of bees at the first to cost 10s. 6d., and neither they nor the swarms to be taken, but to do well, and swarm once every year bees must be naughty indeed if they dare to do otherwise!—what will be the product for fourteen years, and what the profit if each hive is sold at 10s. 6d.?

Year.	Hives.	Profits. £	s.	d.
1	1	0	0	0
2	2	1	1	0
3	4	2	2	0
* * *	* * * *	*	*	*
14	8192	4300	16	0

> N. B.—Deduct 10s. 6d., what the first hive cost, and the remainder will be clear profit; supposing the second swarms to pay for hives, labor, etc.

The modesty with which this writer, who seems to have had as much faith in his bees as in the doctrine that "figures can not lie," closes his calculation at the end of fourteen years, is truly refreshing. No bee-keeper on such a royal road to wealth could ever find it in his heart to stop under twenty-one years, by which time his stock would have increased to more than a million, when, *probably*, he would be willing to close his bee-business by selling them for over two and three-quarter millions of dollars.

THE COST OF HONEY, BY THE AUTHOR OF "BLESSED BEES."

During the hundred years since the above estimate of *possible* profits, I know of no one who has been able to make a more favorable showing than this except the author of "The Blessed Bees." After very careful figuring and verification of the same, John Allen (page 32) makes one colony increase in fourteen years to over a third of a million. Our Mr. Lydserff takes no account of honey, but derives all of his profits from the increase of stocks. Mr. Allen, on the contrary, gets over three-quarters of his profits from the sale of comb honey, leaving the multiplication of stocks, although more rapid than Mr. S., quite a secondary affair. In this centennial year, two more Michigan men—Messrs. Taylor and Hilton step to the front, and, in carefully prepared estimates on the cost of comb honey, so far lower Allen's cost of producing a pound of comb honey as to make it seem quite unnecessary to mention the profits derived from the increase in stocks. Mr. Hilton does indeed incidentally speak of the sale of full colonies, but he makes light of it, and does not mention it in his itemized account. Taylor says nothing whatever about it, as you might naturally expect from a lawyer and politician. Now, in an estimate of the possible reduction in cost, we can not consent to the omission of the smallest item from the account, even to matches and smokewood. In this respect the account of J. Allen is a model, for in it is found such very small items as paint-brush, putty, cord, postage-stamps, etc. As Mr. Hilton gives his report for twelve years, and mentions thirty-five as the smallest number kept, which must have been the first year, his increase by the comforting and carefully verified figures of the author of "The Blessed Bees" would amount to something over two millions of colonies. But it may be that Mr. H. is not as well posted in this branch of his businesss as the college president already referred to, and that, indeed, he may be a full hundred years behind the times, and, like Mr. Lydserff, but doubles his stock yearly. Now, we can prove by a multitude of common bee-keepers that this increase will bring as much if not more honey than a lighter one. This would give him an increase of only seventy-one thousand six hundred and some odd stocks, and we will generously allow him all over the seventy thousand for winter losses (surely he can not have lost more than a hundred a year). If he has sold this increase as he intimates, undoubtedly you will agree with me in saying that, since we are talking of cost in an apiary run primarily for comb honey, the amount received for them ($350,000) should be applied to reducing the cost of the 36,000 lbs. of comb honey he has produced. This would make his honey cost considerably less than the figures he names—in fact, quite a little less than nothing per pound. You will not fail to observe that, the smaller the yield per colony, the greater the profit per pound, which is directly contrary to the teachings of Mr. Taylor, who stoutly defends the now exploded dogma that, the greater the yield per colony, the greater the profits per pound.

In the foregoing estimate, no allowance is made for cost of hives, as it was supposed the honey casually obtained from the increase would more than pay for them. But as we have called for exactness, it will be best to make a separate item for hives, which, however, will make no difference in the net result unless it shall be to still further reduce the cost of production.

In an article by Mr. Taylor in last Gleanings, just handed me, I notice he anticipates me in my corrections on increase, for he says: "It is possible he (Doolittle) intends these (the extra 150) hives for swarms. If that be so, then of course the apiary should have credit for the swarms, which would make a further very material reduction in the cost of the honey crop."

As we are discussing possibilities, and as Mr. Taylor is dealing so largely in "futures," it may be well to call his attention to the Hasty-Hutchinson method of cheapening production and maintaining the supply in poor seasons. This method is also expected to furnish at all times a fine appearing product for the Proctor Steel* Tower grade of comb honey. This will be honey in name only, glucose in reality, with the "bee-y" taste added, but wholly lacking the fine flavor and delicate aroma of the flowers.

Some of the most extensive packers of adulterated honey in the East have approached us for bee-bread. This gives glucose a twangy taste, and causes many consumers to believe it genuine honey. It is suggested that the author of this bee-glucose scheme add, as an especial attraction to believers in the pollen theory, the statement that it will furnish them a desirable home market for their bee-bread. Lastly, Mr. Taylor, when you embark on your voyage of discovery, do not fail to take with you the Punic bee. It is now surmised that the remarkable success of John Allen was caused by his having privately obtained the very first importation of the Punics. The matter of increase will then not be overlooked, for it will not be a secondary affair, while for every other desirable purpose under heaven these bees are modestly claimed to eclipse all other varieties.

DOOLITTLE'S FIGURES SUSTAINED.

Just now a "friend at my elbow" calls attention to the fact that the editor wished me to take sides with Doolittle, and therefore write, not on the lowest possible cost of producing comb honey as already exemplified by the twelve years' experience of Mr. Hilton, or as to be exemplified by the future experience of Mr. Taylor and others, but write on the actual cost with the average bee-keeper. This cost establishes, or should largely establish, the market price. Of course, I am sorry I got on the wrong side, but I can climb over the fence as others have done.

On reading over what I have already written, I judge I may be wrong in concluding that Mr. Hilton has sold much of that increase. If this be so, and he has them standing around in the woods waiting for customers to buy them, and unworked for the lack of students, or even if he has had them worked on shares where the honey cost him a dollar a pound (see page 57, January 15th GLEANINGS), all of these items will have to appear in the account. If we charge up only the interest on their value, $350,000, and say nothing about that dollar-a-pound honey, we shall run up the cost of production to more than four times Doolittle's figures. There must be some important omission in his account which calls for a yearly profit of 111 per cent, or he would hardly be dropping his bee-business, as stated in last *Review*, to engage more extensively in the supply-business. Or is it true that we have been paying that much or more profit on our hives, sections, crates, foundation, etc.? If so, how would it be to have now a discussion on the cost of supplies? Mr. H.'s account says nothing about cost of shop, honey-house, honey-extractor, wax-extractor, smokers, etc., the cost, interest, and wear and tear of which for twelve years would amount to more than a thousand dollars at Taylor's low estimate. The account also says nothing about rent for the bee-yard, which in twelve years, at the low price the average bee-keeper pays, would amount to from $150 to $200; and as Mr. H. keeps bees successfully without any of these necessaries of the average bee-keeper, and as he has had no disastrous winter losses to report, no radical and expensive changes in hives, fixtures, or management to meet the changed requirements of the markets and of improved bee-keeping during the past twelve years, no dollar-a-pound honey, (did I promise to say no more about this?) and has no expensive mistakes or other items of loss to charge to the business, we conclude he is so far above the average bee-keeper that his account can have but little bearing on cost of production with the average honey-producer. Further confirmation of this is found in the cost of manipulation, which is given at fifty cents per colony, which I doubt whether another skillful bee-keeper in the United States can report as low for as long a time.

Mr. Taylor, in his last, calls for "critically exact statements, with full details of the actual necessary expense of money and time." After these are obtained, the present bone of contention will still remain; the amount the average honey-producer may have apportioned to him as wages or salary before the cost of production can be determined. We have an illustration of this in the account of C. F. Thomas in March 15th GLEANINGS, in which this item is left out. As I understand, Mr. Thomas, in estimating profits in his hardware business, does not reckon in a salary for himself as a part of the cost of conducting his business. But let me say to him, and to honey-producers who figure in the same shortsighted way, that, if a tax on net profits were likely to hit them they would hustle around for a salary fully as lively as Doolittle, and probably make it quite as high. It seems to me that Mr. Doolittle has stated the case fairly in his last by saying that the average bee-keeper or bee-keepers on an average could get two dollars a day, or six hundred a year, without board, in some manufacturing town; and that this amount, when he is engaged in the production of honey, is as much a part of the cost of it as any other item.

To make a long story short, we will say that honey-producers on an average earn or make a hundred dollars a year outside of their business. This will leave five hundred to charge to their business. Then accurate statistics will give all other data necessary to show actual cost. In the last quotation from Mr. Taylor, the word "necessary" should have been left out by him; for, in the actual expense account, past, present, or future, will be found many items not necessary, and such will have to be audited if we are seeking the real cost of honey-production in this country. If the lowest possible cost is sought by taking only the accounts of the most skillful apiarists, the same items will be found, though neither so numerous nor so costly. The difference between the average and skillful cost will show the profit of being skillful, for the market price will be usually regulated by the general cost. If the past governs or forecasts the future (and we have no right to judge otherwise), then will unexpected and unavoidable reverses always be a very heavy item in cost of production. For Mr. Hilton and Taylor to present accounts and estimates with the reverses and losses left out is to overlook one of the *most certain* sources of cost; it is to disregard the fact that man is and always will remain a costly blunderer, and that his environments are such that his business is liable to constant loss from drouth and flood, fire and frost, disease and death, etc. At the end of a few years I predict that Mr. Taylor will report that

> The best-laid schemes o' mice an' men
> Gang aft a-gley;

for, in addition to the items he now specifies as sufficient, he may have to chronicle heavy losses from some new bee-disease or enemy; from disastrous winter mortality in his locality; from selling honey at 10 cts. instead of 15 cts., caused by a free use of H. & H. methods or other causes; from having his range overstocked, thereby reducing his average from fifty to thirty pounds per colony, and depreciating his plant in like proportion; by expense of changing his Heddon hive and fixtures to some hive better adapted to the Punic (or *Apis dorsata*) bee; and from other unexpected and unavoidable causes.

---

* *Steel* should be spelled with an *a* when bee-glucose is sold as the author claims a descriptive mark should be used. The Proctor Steel Tower is to be erected on the Chicago World's Fair grounds, and will be 1100 feet high, or 100 feet higher than the Eiffel tower. As no superlative has been found for Chicago top grade, this is suggested.

So far as my observations extend among good bee-keepers, the margin of profit is small, although the expense account is usually very carefully looked after. I am, therefore, in the fullest sympathy with any effort to ascertain actual cost and to cheapen production; and because a knowledge of the former would be an efficient educator to that very large number who now produce honey at a loss, while a solution of the latter is truly the "sheet anchor" of the specialist.

I wish to assure the readers of GLEANINGS that I hold Messrs. Taylor, Hilton, and Hutchinson in very high esteem as men and bee-keepers, and that any criticism I have made applies only to their method of approaching the solution of this question, which I hold to be unwise; and, coming from the sources it does, it is injurious to our markets. As the editor has truly said, "We can not talk prices up," but we can easily talk them down. P. H. ELWOOD.

Starkville, N. Y., March 26.

[The above would have appeared in our issue for Apr. 1, as announced; but on account of the sickness of Mr. Elwood it did not reach here in time for that number. The discussion has now been well balanced up, both sides being well represented; and for the present we deem it best to have it closed, since the arguments have been made with different standpoints and with different ideas as to what constitutes cost.

Although Doolittle's side has had "the last say," it may be a little comforting to t'other side to know that we are still on their side of the fence. Taylor argues on the possibilities and actual necessary expenses, and not on average results as obtained by the average bee-keeper. As we view it, if there is a possibility of reducing the cost of a pound of honey we ought to grab at the least straw; in other words, that which is in the range of possibilities may be made to become an actual achievement. Therefore is it not pertinent to look well to what are necessary and what are unnecessary expenses? *If* we can cut off the unnecessary outlays, is there not a strong probability that Taylor's figures may be some day realized? Although we are supply-dealers, we ought to say, in all frankness, that it is the biggest piece of folly for bee-keepers to throw aside too hastily the old and adopt the new. This has been done a great deal, and it counts pretty heavy in the cost of producing honey. Nor is this inconsistent with what we have already said in these columns. We have repeatedly advised bee-keepers not to cast aside their old loose frames all at once, and adopt what we feel sure is better—self-spacing frames. The change should be made gradually, and that, too, on the assumption that the trial of a few justifies the introduction of more. What we have advised and still advise is this: When you *need* more frames, get the latest self-spacing. Taking the whole thing in a nutshell, Messrs. Doolittle and Elwood have argued on the actual results attained by bee-keepers; Mr. Taylor, for what *might* be attained, putting it, as it seemed to us, in the range of possibility. Taking the whole discussion, even if we are more on the side of Mr. Taylor, we find we have at least an arm and one foot over on Doolittle's side of the fence, and it is very possible that a few months or few years later will draw us clear over, coat-tails and all. Mr. Elwood touches on an important matter; viz., we can not talk up prices, but we can easily talk 'em down. The impression should not go abroad that the average bee-keeper realizes in sales double on the cost of his honey, for these are not the facts. If the middlemen think bee-keepers as a whole are making 100 per cent on their investments they are going to work a scheme to get a part of the per cent. No, let us clearly understand what are facts and what are possibilities. If we produce comb honey *now* at, say, 8 or 10c per pound (it never ought to cost 15c for the average season) perhaps in the future if we look well to possibilities we may produce it for 5c per lb.]

MANUM AND HIS NEIGHBOR.

CONTINUED.

"Manum, at what stage of advancement do you prefer to remove the queens?"

"Well, Charles, usually on the first discovery of eggs in the queen-cells. Last year I removed a few on the 28th of May, and by June 17th all were removed. I sometimes take out queens from such as are full of bees and brood, even if there is no sign of swarming, in order to save hunting for the queens later on. The most tedious, tiresome work I have to do is hunting out queens in these full colonies. Where I have to work at it all day there is more work than pleasure in it."

"I believe you experimented in caging the queens in the sections, and leaving them on the hive where the bees could have access to them, did you not?"

"Yes; I tried it to some extent, but I can not give a favorable report yet. I want to try it another season before I can decide. In some instances it worked successfully, while in many others it was a failure. I believe, however, that the plan can be made a success if the queens are liberated at just the right time; but I have not as yet discovered *just* when the right time is."

"What are the disadvantages to this plan, if there are any?"

"In the first place, I believe it is an injury to the queens, when confined from 8 to 12 days where they can not lay eggs. This sudden check from laying, which is contrary to their nature at this season, seems to be an injury from which they do not seem to recover, because, when liberated and not rejected (which is often the case), they will lay eggs here and there all through the hive, and then swarm. But I find that, where they have been caged but 5 to 8 days, they behave much better; hence I am in hopes yet to make this plan a success. Charles, there are so many things about this bee-business that I don't understand, that I begin to think I never shall know it all."

"Did you think the bees worked any better where the queens were caged than where they were removed entirely?"

"No; I could not see that they did."

"Then what would be the advantages by caging, over the removal of queens?"

"Well, where one does not sell his yearling queens it saves introducing new ones, as these are already introduced; and I fancied where there was a laying queen present they were not as liable to start queen-cells as where no queen was present; however, they did in some cases start cells fully as soon, and as many of them."

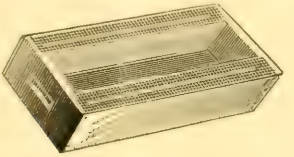
"Now, Manum, what would you advise me to do, should I decide to run my two apiaries alone—to remove the queens entirely, or cage them?"

"Well, Charles, taking all things together I would advise you to remove the queens in preference to caging them; however, you might experiment in caging a few. By so doing you might discover some very important points which would be beneficial to other bee-keepers. It is not for one person to discover or know all. We can all help a little. There is a large field of knowledge in nature that is yet undiscovered, with room enough for all to work in. Hence let us all take a hand in the work and then compare notes."

"Well, well, Mr. Cox! walk in. Charles and I are having a convention all by ourselves."

"Yes, I see, Manum; and I am sorry I did not come in sooner. Charles living so near you he can step in and talk bees at any time; but I am so far away I have to be satisfied with what I find in GLEANINGS. I came in, Manum, to ask if I could see your new feeder that I hear so much about among bee-keepers, and to ask if it gives you satisfaction."

"Oh! yes, Mr. Cox; you can see it, and here it is."



MANUM'S FEEDER.

"Why, Manum, it is a different-looking thing from what I supposed it was. Why! it is a regular box. Won't it leak?"

"No, not if properly made—at least, I am not troubled with their leaking; as you will see, they are thoroughly made."

"You use them, I hear, for feeding back extracted honey. How do you do it?"

"There, Mr. Cox, you see they are just the width and length of my clamps; and by placing one on a clamp of sections you will see that it is so arranged that the bees can pass up from the sections into the feeder and back again, no matter how many tiers of sections are on the hive; just place the feeder on the top tier, and it will work like a charm."

"How much does the feeder hold?"

"Well, those made for my size of clamp hold 16 pounds of extracted honey. You know my clamps are only half size—in other words, it takes two to cover the top of my brood-chamber; hence when I wish to hurry up matters I put on two feeders."

"Charles, have you tried these feeders " Mr. Cox asked.

"Yes," said Charles. "I have 20 of them, and intend to make 100 more. They are the best feeder I ever saw. My man told me last fall that he wished I would give away all my old feeders and replace them with Manum's new kind. I have urged Manum to have them patented, but somehow he doesn't seem to care for patents; whatever he invents he *gives* to the public."

Mr. Cox asked, "Now, Manum, there is another thing I want to ask you. What do you think of the Porter escape? Have you ever used them?"

"No, I have never used them. Mr. Porter sent me two last fall, but too late in the season to give them a trial, hence I can not speak from experience. But simply seeing them convinces me that they are a good thing—yes, a *perfect* escape."

"Now, Manum, why is it that we heard nothing from you through GLEANINGS for so long a time?" asks Mr. Cox.

"The fact is, I have been very busy since last May, as you must already know. Besides the care of all my bees I have had to look after and ship my crop of honey, prepare and feed the bees for winter, and, in addition to all this, I have made extensive repairs on my house; and, furthermore, I felt it a duty to entertain the *new queen*—a pleasant duty, which, of course, I did not neglect. I hope now, however, to be able to talk to the readers of GLEANINGS several times before the busy season is upon us. I will add, before you go, Mr. Cox, that the new 'queen' (Mrs. Manum) manifests much interest in bees; and the symptoms are that she will be a great acquisition to our calling, inasmuch as she proposes to acquire a knowledge of the business and take an active part in the apiary.

Bristol, Vt., March 23. A. E. MANUM.

[We are glad, friend Manum, that you have given us more light on this question of caging queens or removing them to prevent swarming. There is a great deal of disagreement on this subject, and we need more facts. Still, there are those who make it a success, as you do. In regard to the feeder, if we understand it, it is very much in principle like the one introduced by Dr. C. C. Miller, and bearing his name. The thing has since then been improved at the Home of the Honey-bees, although the principle is kept the same. It is an excellent feeder, and we don't wonder that you and your neighbor like it; that is, if it is the same feeder. We have no doubt that you originated your feeder without the knowledge of the one gotten up by Dr. Miller, or at least you had not taken particular notice of it when it was illustrated and described.]

WRITING FOR THE BEE-JOURNALS.

ANSWERING QUESTIONS OVER AND OVER AGAIN BY LETTER THAT ARE ALREADY COVERED IN THE TEXT BOOKS.

Only a little over 30 years have passed since the advent of the first bee-paper in our country; but what a change has been wrought along the literary lines of our pursuit! Thirty years ago scarcely a dozen could be found who would even dare to write on the subject of bees for publication; but now we have hundreds who so write; and we find that the matter has assumed such proportions that a whole number of one of the leading bee-papers (the *Review*) is devoted to the discussion of the importance of "writing for the bee-journals." But I did not start out to tell who should or who should not write for the bee-papers; but of some of the things which a writer to such papers has to encounter by becoming prominent in this respect. In that memorable issue of the *Review* alluded to above, Mr. Clark says, "Mr. Doolittle writes too much." and I have about come to that conclusion myself, and here propose to tell the readers of GLEANINGS some of the things which have driven me to that conclusion. I have written to the extent of answering every letter and postal card that has ever come to me so far; but just how long I shall keep it up, I do not know, for I have of late been impressed with the idea, that, after keeping this thing up for fifteen years, I ought to have a vacation. Here are some of the things which have caused these thoughts to come to my mind:

A person in Florida writes, "In a back number of GLEANINGS I saw an article from your pen about the different kinds of willows. As I have embarked again in bee culture, I should like for you to send me cuttings of all the different kinds of willow in your vicinity. Please label them all nicely so I can tell them. We have only the swamp-willow here. Inclosed I send three postal cards for postage, not having stamps on hand. If not enough for the postage, I will pay the remainder here. Your articles are a great help to me. Long live GLEANINGS."

I heartily indorse the last sentence; but in order to indorse it long I must live myself. I am also glad to know that my articles help some along the rough and uneven way of apiculture; but will these things and the three postal cards warrant me in tramping several miles for willow-cuttings, carefully labeling them, packing them securely, and taking them one mile to the postoffice? If not, will you, Mr. Editor, and the readers of GLEANINGS, tell me what I shall do?

Another writes: "In a late number of the *American Rural Home* I see an article from your pen, on bees, which interested me very much. Will you please write me all about how to manage bees, how to build a bee-house, what kind of hives are best, and how much profit I can expect out of the business? Please give full particulars in the matter."

Clark says I write too much, yet here is a man who apparently doesn't think so, but wants me to write a book for his benefit, and present it to him in manuscript, without even inclosing a postal card to pay a small part of the postage. He little dreamed that, when I came to his letter, I had already been answering questions for an hour or more, or that there were from five to ten unanswered letters on my desk, with the hour of bedtime at hand, or that I was tired and nearly exhausted with the labors of the day. I want to accommodate all, but must be excused from writing for any one the details of what he can procure through the papers and books published on bees. In this case I wrote him that he would find all of his questions answered in such and such books, naming them; and if he wished to keep up with the times he should take one or more of the different bee-papers, naming them also. As this required too much writing to go on a postal card, of course it required an envelope, sheet of paper, and a two-cent stamp. It seems all should know about this envelope, paper, and postage, without being told; yet not one in four who ask questions similar to the above incloses a stamp. A stamp to them means very little; but to the one who has followed answering all such questions for fifteen years, it means a small fortune.

Another says, "I wish to thank you for all of the good articles you have given us in the bee-papers for many years. I always turn to your articles the first thing when I get any of the papers which you write for, being sure of a feast every time. Now, if you will grant me a favor you will lay me under renewed obligations to you for your kindness. On a separate sheet you will find some questions which I wish answered. If you can find time to answer these you will greatly oblige. Yours truly, —— ——."

By this time Mrs. D. has retired, but has not gone to sleep, so I call to her, telling her of the good words spoken above, and how glad I am that we could be the means of doing some good in the world. She replies by asking if I have looked at the questions.

"No, but I will."

The "separate sheet" proves to be a whole sheet of foolscap paper written solid full of questions, which begin: "1. I think I have foul brood in my apiary. Will you receive a sample from me and tell me if it is such? 2. How do you tell foul brood? Please describe it so minutely that I can tell whether I have it or not; also tell me just how you would work to cure it." The 3d, 4th, and 5th questions are similar to the above, on foul brood. "6. How many colonies of bees do you keep? 7. How do you manage them during swarming?" and so on down to the end of the sheet. What shall I do? I dip my pen in a different-colored ink from what the letter was written with, and right above every question give the very best answer I can in the space there is between the lines, directing to different books and articles as much as possible, in the mean time remembering how good old Elisha Gallup used to bear with me when I bothered him in the same way, and trying to be glad to repay him by doing for some brother or sister what he kindly did for me. In this way I keep on, and probably shall as long as questions are sent in. Being a little worn to-day I felt as if a little knowledge of what a writer has to do might cause some to ease up a little on these private questions, and help others to know that the bee-writers do not all lie on "beds of roses," as well as to relieve me a little by not keeping all of the good things to myself. G. M. DOOLITTLE.

Borodino, N. Y., Mar. 16.

[We thoroughly appreciate your situation, friend D. As editor of GLEANINGS it is one of our duties to answer questions. Those that are not of sufficient importance for publication are answered by letter. But unless *your* querist is kind enough to inclose you something, you will probably get no pecuniary returns for your pains and trouble. A correspondent certainly ought to inclose a stamp, or, better, a stamped and addressed envelope, to bee-keepers of whom they desire information; and where he calls for very full answers he ought to ask his teacher, as it were, to send in his bill. As editor of GLEANINGS, however, we are prepared to answer all the questions, or at least ought to be, without even so much as a stamp or stamped envelope; and while our replies have to be very meager, often referring the querist to our A B C of Bee Culture, it is the best we can do. It is a little curious why people will ask questions that are very thoroughly and well covered in nearly all the text-books. Every once in a while we are asked to give very full particulars as to when and how to transfer. There is not a general text-book on bee culture, however poor, but answers both of these questions fully. There are many others of a similar nature that we invariably refer to some page or paragraph in our A B C book.

RAMBLE NO. 57.

"OUT ON THE OCEAN SAILING."

When on my day of life the night is falling,
  And in the winds from unsunned spaces blowing,
I hear fair voices out of darkness calling
  My feet to paths unknown.

We can little imagine the size of a country until we commence to travel over its surface. Everybody knows that Texas is the largest State in the Union; but few people stop to think which is the next largest. It is California, and it is noted for its magnificent distances. Its entire coast line is 900 miles. From San Francisco to Los Angeles it is about 440 miles, and a journey by steamer gives the traveler two nights, or nearly 48 hours, on the ocean. My face was set toward Los Angeles, and a sea-voyage had been an experience I had often dreamed of, but never imagined I should have the privilege to make one, and especially on the Pacific. This was, then, an opportunity not to be slighted.

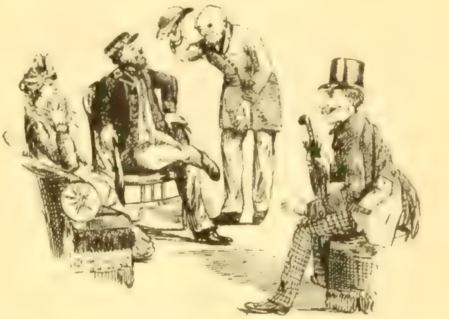
The good steamship Queen left her wharf at San Francisco at 11 o'clock A. M. on Sunday, the 21st of October; and if all was noisy bustle when we started, it was quiet enough for any Sunday when we left the city; and if I had any misgivings about starting on that day I had none after I had been out a few hours, and only wished that all of those who were laboring and in the pursuit of questionable amusements on the Sabbath were sailing out upon the ocean where all is so quiet, so grand, and so soul-inspiring. As we passed through the Golden Gate the fog was rolling in from the ocean; and land, though quite near on either side, could not be seen. The hoarse fog-horn on the steamship would blow every few moments, and an answer would come from another deeper-toned horn on some dangerous point on the shore. We soon experienced a change, however, and knew we were out upon the broad ocean, from the rise and fall of our ship as she encountered the regular ocean-swells. The fog rose after a few hours, and the steamer was out about 25 miles from the shore, and kept about that distance while between stopping-points. It was a pleasant sensation to stand on the highest deck at the stern of the vessel, and look forward and see the prow rise and fall as we went over the swells. The sea-gulls kept us company. It is said they can tell when meals are in progress from the savory smells that arise from the culinary department. However this may be, hundreds of them were always on hand to dive and squabble for the refuse that was thrown overboard after every meal.

A small amount of shipping is seen on this coast compared with the Atlantic. Many large cities in the East make an enormous coast trade; but their absence here, of course, diminishes the number of ships; and from the barren wastes of treeless mountains all along the coast it will never reach great magnitude.

Our state-rooms were well provided with all appliances necessary to aid a person to become seasick; but the sea was so even-tempered, so pacific, that none on board were thus afflicted. If there were any, they kept it very quietly to themselves.

The long quiet hours of the day were passed by many in their state-rooms, reclining in their berths, reading or sleeping, mostly the latter, for some people think they can sleep better in the day time when they don't want to than in the night when they do want to. This fancy, perhaps, holds good in other places as well as on shipboard. In the evening there was a gathering in the grand saloon. Some one leads on the organ, and several gospel hymns are sung; and, did you imagine it, my friends? those hymns are sung all across our land, under every condition of life, in the city and in the camp; and in the most unexpected places some favorite air will be wafted to your ear. Who shall say the tiny seed is not taking root in the apparently barren ground? After the songs, we listen to the fat and jolly captain who is entertaining a group of ladies by telling them that no one is seasick except those who are scared; that men are more liable to be seasick than ladies; that the average man's hair would stand on end when the waves begin to roll.

A sedate man in the corner wanted to know how a woman's hair could stand on end when it is always tied down. He said that, while it was perhaps a historical fact that a woman's hair never stood on end, there were also men whose hair never became erect. He further said that no high waves or lions, nor even ghosts, could affect him. There was a prospect of some betting on the subject; but as no lions or ghosts were just then handy, that scheme was dropped. Some one then proceeded to investigate the man's head, when, lo and behold! the man was baldheaded. The laugh went merrily round; but the captain insisted that, though bald, a man could have the same sensations, which, to all intents and purposes, were the same as though he had the hair of a Samson. So the paradoxical question is open for debate: "Can a baldheaded man become so frightened as to make his hair stand on end?"



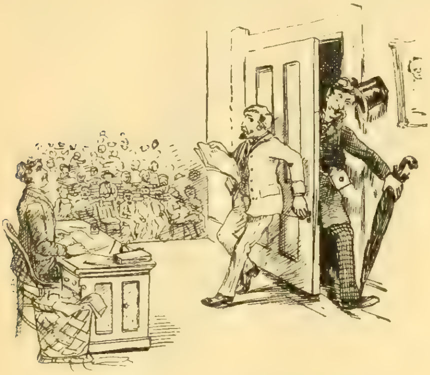
"CAN'T MAKE MY HAIR STAND ON END."

There are but few islands in sight until we near the port of Santa Barbara. About 25 miles out from this point are the islands of Santa Cruz, Santa Rosa, and several smaller islands. Santa Cruz is the largest, and it has been suggested that this would be a good location upon which to breed a pure strain of bees, as the selection would receive no interference, the location being completely isolated. There are no bees upon these islands; and if the many fogs would not interfere, the plan may some time be tried. These islands are something of a resort for pleasure-seekers, and on their shores are found seals and beautiful shells.

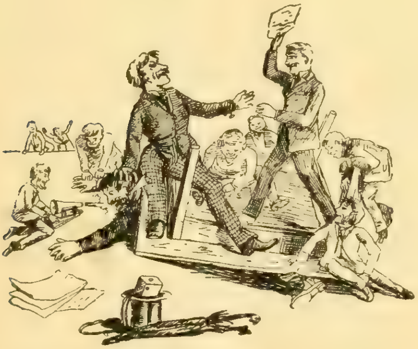
San Pedro is the port for Los Angeles. Our vessel could not run up to the wharf, so several hours were spent in hoisting out a great amount of freight upon a lighter, and lighter and passengers were towed to port by a small propeller. Twenty miles by rail, and I arrived in the beautiful city of Los Angeles.

Having corresponded with Mr. Brodbeck, the secretary of the Southern California Bee-keepers' Association, I desired to become personally acquainted with him, and found him wearing his life away in the dry-goods establishment of Mr. Coulter. The next morning the Association met in the W. C. T. U. hall. This may be a late date to report the proceedings; but as they were very "*uneek*," and were described by the local press as a bamfuzzled crowd, a few words in relation thereto may be admissible.

Several of the leading bee-keepers desired to change the Southern into a State organization. The secretary, with the consent of a majority of the executive board, issued a call to that effect. The president, however, had a very fatherly interest in the old organization, and, soon after the meeting was called to order, it was evident he meant to fight it out on that line, even if it occupied the entire time of the convention. After a long struggle a vote was taken, and the State lost by one vote. The treasurer then took up the call issued by the secretary, clause by clause, and gave our genial friend particular fits. In the last clause of the call, the secretary stated that "Rambler" would be there; but as the constitution of the association was so narrow as to admit only those who had an ownership in bees, the treasurer became so excited over this "Rambler" portion that he figuratively slammed the door in the Rambler's face, and exclaimed that no Rambler should get into that convention as long as he had power to prevent it. The secretary and the Rambler kept perfectly sweet; and when the gentleman—no, the treasurer, had exhausted himself and the subject, the convention proceeded to the election of officers; and, remembering the hours of wrangling, the tables were nicely turned on the treasurer, and another man elected instead—Mr. Abbott, of Pasadena. The secretary was made happy by having his action indorsed by a unanimous re-election. The Rambler also felt as happy as a bright sunflower. The ex-president tried to put in a few more remarks, but nearly every bee-keeper arose and buzzed so loud that his voice was drowned, and it looked as though a swarming-out mania had taken possession of them. Mr. Abbott, the new treasurer, took the chair, the buzzing ceased, and the swarm (of bee-keepers) alighted in their seats again.



NO RAMBLER ALLOWED IN HERE.



TABLES TURNED AT THE CONVENTION.

Conventions are supposed to be held for mutual instruction, advancement, and the having of a fraternal era of good feeling; but this convention had so much wrangle that but little time was left for mutual benefit, and many returned to their homes not satisfied with the results. The moral learned is, that associations are not formed for the benefit of any one person or clique, but for the many; and when their interests are ignored, there is always more or less music in the air.

Quite a number of bee-keepers live in Los Angeles, and in that other charming town, Pasadena; but while their homes are in town their apiaries are miles out in the mountains, which are ever present in this portion of California.

There seems to be a sort of mutual understanding, or an unwritten law, among bee-keepers in relation to the rights of location. If a person secures a prior right by establishing an apiary in a certain field, it is seldom that a man will crowd in where he is not wanted, or where it will be a detriment to his own interests as well as to his neighbor's.

Wishing to find an apiary in the sage district, I wandered due southeast from Los Angeles; and until further notice the shades of night and the Hotel Temescal will hide the

RAMBLER.

SPRING DWINDLING.

JAMES HEDDON DECIDES IN FAVOR OF OUTDOOR WINTERING; HE PREFERS OUTSIDE WINTER CASES, AND WHY; HOW HIS CASES ARE MADE, ETC.

The time is drawing near when we shall read from the pens of various bee-keepers the following: "My bees wintered pretty well, but I lost heavily by spring dwindling." Now, Mr. Editor, I am not going to say any thing I haven't said before, nor offer any arguments that are new, except only as all arguments are new until they are answered. Immortal youth is one of the attributes of an argument which can not be answered. Neither am I going to suggest any methods that I haven't written for bee-papers long ago, and practiced even longer. Your readers change, and it may be of value to some of your present subscribers to know what methods I have found most successful in wintering and springing an average of 500 colonies during the past 15 years in a locality where bee-diarrhea seems to be right at home nearly every winter.

As I have before said, and feel that I know, the excreta of bee-diarrhea is undigested pollen; and pollen-eating during cold and confinement is the cause of that malady, compared with which all other causes of winter losses combined sink into insignificance. Again, I claim as heretofore that there is no such thing as spring dwindling among bees which are well wintered; that a normal colony of bees never dwindles away to nothing in spring after the time comes when they can gather pollen, and fly most of the time, unless the bees of such colony had intestinal inflammation when they crossed the line between winter and spring, as we term it. Confinement without extreme cold will produce the malady when the food is right for it; consequently, during all such winters as the one just past, and three or four preceding it, in Southern Michigan bees are safer properly packed outdoors than in any special repository. Every winter I have had them both ways, and have observed results in other apiaries round about.

But now comes the question, "How should bees be packed for outdoor wintering?" I have packed in so many different ways during the same and different winters, that I feel positive of the superiority of the one I am about to describe; and the reason of this article at this date is because I have found that every colony wintered indoors should be packed the same way for springing, whether they are partially diseased from wintering or in perfect health; because, even if the latter, and no spring could kill them if not packed, even these healthy colonies will be enough stronger when the surplus harvest opens, because of this packing, to repay the owner several times over for all cost and trouble. I once discussed this question with W. Z. Hutchinson, I taking the opposite and he my present position; but I afterward found out my mistake, and admitted it — yes, declared it several years ago.

I pack as follows: I make a box of common lumber two to three inches larger than the hive all around. It has a tight bottom, and a cover shutting over like the lid of a trunk, but without hinges, of course. After taking the hive from the bottom stand, and placing the box thereon, pitching it 15 to 20 degrees forward, I put a solid 1½-inch dry sawdust in the bottom, set the hive inside on the sawdust, with an arrangement to make the entrances correspond; drop in a bridge to make a closed entrance which will keep out the packing; then fill in on all sides with sawdust lightly packed, rounded up at the top, the cover of the box put on and weighted down. I use no upward ventilation nor absorbents about the hive—just leave the plain board cover glued fast. The box cover must not leak, because it lies flat and solid on the sawdust, which would absorb all the water that might leak through, injuring the hive and box cover, but would not hurt the bees at all. Now listen. Here is a favorite point in the arrangement: My hives are painted "dead" white—white to reflect the sun's rays, making them much cooler in summer in the early and late part of the day, when the sun can shine under my shade-board sufficiently to strike the brood-chamber; "dead," to prevent glistening. These packing-boxes, however, are painted very dark to absorb the solar heat during winter and spring, and the close packing without any interspaces is what conducts this heat clear through to the combs and bees. The above is my main reason for not desiring a greater space between the hive and outer case than from two to three inches, and for using material as solid as sawdust tightly and closely packed between covers, as elsewhere.

Just here I think I hear some one say, "If you are going to pack like this, just for springing colonies taken from the cellar, why not pack them in the fall and leave them out, depending on outdoor wintering, and done with it?" My reply is, "Yes, why not? Certainly it is the best, considering all trouble and expense, except in extremely cold winters, compelling continued confinement, and these are the exception and not the rule in Southern Michigan." I believe the outdoor plan, with such packing, which more than pays for springing alone, to be first choice.

Your readers will be able to judge from the above in what latitudes and localities I would consider this method of outdoor wintering preferable. The amount of sunshine has much to do with it.

The above are my most earnest conclusions, based on several years' experience and observations. What are yours? JAS. HEDDON.

Dowagiac, Mich., March 23.

We do not know much about spring dwindling—that is, what causes it—whether it is a malady peculiar to certain seasons or whether it is due to the consumption of too much pollen. In our locality we have taken no pains to select combs without pollen for wintering, and yet for the last six or eight years we have had very little spring dwindling.

You may be right, and you may be wrong in regard to pollen; but we are certain that you are pretty sound on the wintering question. While we have been making all this noise about non-absorbents and sealed covers, we presume you have been using them for several years. By the way, there has been a good deal of foolishness shown as to who was the first one to discover the sealed-cover idea. As the expression goes, it is "older than the hills."

We have no doubt that your winter cases give excellent results; and we are sure that you are right in advocating that cellared bees ought to be protected after being set out in the spring, for a time at least. Our winter cases gave us most excellent results. It may surprise you a little to know that those with dead-air spaces wintered the bees just as well as those in which the same spaces were packed with chaff or planer shavings. It may not do so in your locality, but it does with us. Our winter cases, as you may know, are made of ⅜ lumber, and only 2 inches larger inside all around than the single-walled hive is outside. It has no bottom—it simply slides down over the hive, padded sticks being on the inside bottom edge to keep out the cold. A ¼-inch board is then put on top of the hive, and the bees are allowed to seal it down, which they will do, of course, if put on in time. Above this thin board is a chaff cushion 2 inches thick, and the winter case is then covered by the ordinary hive-cover.

We remember that you once took the ground that indoor wintering in your locality was better; but now it is a pleasure for us to observe that you decide for outdoor wintering for average winters. For our locality we are sure that it is the better way. We are equally sure that, for very cold localities, the cellar plan is the better. The great trouble with localities like our own, and perhaps yours, is that bees in the cellar are apt to be noisy and uneasy because the weather outside is at times too moderate.]

ARE CLOSED-END BARS OF BROOD-FRAMES PREFERABLE TO OPEN ONES?

READ AT THE OHIO STATE BEE-KEEPERS' CONVENTION, CINCINNATI.

I suppose that, if the question were put in other words, so as to read, "Are the standing closed-end Quinby brood-frames preferable to the Langstroth hanging ones?" the general verdict would be that the latter are preferable. Yet there is undoubtedly a growing sentiment against loose hanging frames; but that it will ultimately lead to the adoption of a closed-end brood-frame, I do not think. Although many excellent bee-keepers now use them, and would have no other, still my faith is stronger to-day than ever that some form of the Langstroth hanging frame will ever be the most popular, and will serve to perpetuate the memory of the man who has done more toward the advancement of apiculture than any other that ever lived; who lifted our pursuit from an unprofitable and unsatisfactory investment in "straw skeps" and box hives to a pursuit at once profitable, respectable, and highly fascinating to a large class of our people. That this revival of apiculture from the state of obscurity into which it had fallen was due to the Langstroth invention, there is not one who to-day doubts. That it still has merits over every other invention of a bee-hive, either ancient or modern, it seems to me is so far proved by the history of apiculture in the last forty years that the question is hardly worth discussing; and that these merits lie chiefly in the superiority of the hanging frame is equally apparent. So it would appear, that, after the general approval of the bee-keepers of the civilized world for forty years, we may well conclude that the principles of the Langstroth hive will survive and become the dominant ones in the popular hives of the future.

The present tendency against *loose* hanging frames is not necessarily a tendency toward the use of closed-end brood-frames, but, rather, toward some practical method of spacing and fixing the hanging frame. This we have had for some years in the Hoffman-Langstroth frame, which of late has undergone a further improvement by the Root establishment at Medina, so that, as now constructed, it is without objection, and fulfills every function claimed for the closed-end frames, and yet is about as readily movable as the old style of the L. frame. However, in a hanging frame only 7 inches deep, which I use, I prefer to space and fix the frames by a very light form of the Van Deusen metal corner, as it spaces exactly 1⅜ inches from center to center, and does not interfere with the ease with which the frame may be taken from the hive. It is, therefore, my opinion that, between these two methods, the public need not look further for a practical means of keeping the Langstroth frame in its place. The preference, then, must be given to brood-frames with open end-bars. Dr. G. L. Tinker.

New Philadelphia, O.

[The first sentence of the last paragraph gives the true statement of the case. So many have inferred that, *because* we do not recommend the loose frame, therefore we argue for the closed end. Not so; as the doctor well states, some method of accurate spacing is demanded; and that, for the L. size frame, the Hoffman end-bars seem to meet the requirements. As to a seven-inch frame, the Van Deusen may be better.]

AUTOMATIC SELF-HIVERS.

PRATT'S DEVICE CRITICISED.

As I invented the first self-hiver, it is quite natural for me to take quite an interest in all that is said about them. In Gleanings, page 199, I see that Mr. Pratt illustrates and describes a device for self-hiving bees, which he claims as his own invention. Well, it may be that it *is* all his own. I want to say that Mr. P. and myself have talked a good deal about self-hivers in the last two years.

Last season I remarked to Mr. P. that I did not know but that I should have to arrange my swarmer so as to compel the bees to pass out through the new hive in order to hive *all* the bees that issued with the swarm, as, by being compelled to enter a new entrance on their return, not all the bees that come off with the queen would find her and enter the new hive. I also stated that there were strong objections to placing one hive before another, and thus compelling the bees to travel such a long distance in order to reach their combs on returning from the field.

I will describe and illustrate, in Fig. 1, the most practical self-hiver tested; and this has been thoroughly tested, and does its work well.

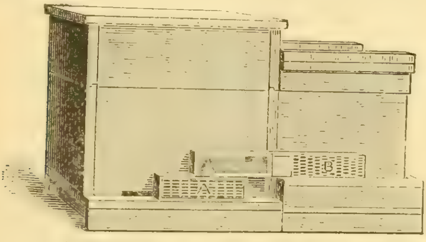


FIG. 5—FULL COLONY. FIG. 6—DECOY HIVE.

A and B represent the self-hiver.

The hive at the left is supposed to contain the colony; the one at the right hand is a sort of skeleton (or decoy) hive. In the decoy hive should be placed one dry, clean brood-comb. Several days before a swarm issues, the bees will be busily working on the comb; and when the swarm issues they enter the new hive. The queen quickly enters box B, and is followed by more or less bees; and when the swarm returns the bees readily find their queen and settle down to business. In case there are not bees enough to make as large a colony as is desired, the parent hive should be removed. Now, no one can reasonably object to this; as the old or new swarm should have a new location, and experienced bee-keepers would advise making the young swarm as strong as possible, it is certainly a great advantage to do so. I consider the above arrangement for a self-hiver the most practical of any yet described. In working for a practical self-hiver I kept in mind the fact that the entrance should be as free of any sort of obstruction as it is possible to keep it, and at the same time have a swarmer attached to the entrance, which, in my opinion, is of itself all the obstruction that should be there. I also kept in view the fact, that the swarmer, in order to come into general use, should be sold at a low price.

I have no doubt that the Pratt device will hive the bees. It seems to me that he has adopted the same principle for trapping the queen that I have been granted a patent for. Therefore the Pratt swarmer, like all the others, is an infringement on my claim.

Some time within six months my good friend Dibbern took considerable space in this paper trying to make your readers believe he had devised a swarmer that would hive a swarm of bees every time. Before Mr. D. got through it was found that his swarmer had *never* hived even one swarm of bees. All that he could claim that it had done was to catch the queen and a few bees. I should say that it catches about as many bees, and works about the same as the drone and queen trap. By the way, Dr. G. L. Tinker says the queen-trap is as good a swarmer as he wants. Well, if one is in the apiary most of the time there is no better arrangement for managing swarms when one issues than by using the trap. Where the trap is used, the bee-keeper is not obliged to drop his work when the swarm comes off; he can take his time to hive them. If no hive is ready when a swarm passes through the trap, just place a box near the hive the bees issue from, so that the trap will be about the same distance from the ground as when on the hive, and I will guarantee that not one bee will return to the old hive, but all will go to the trap and cluster with the queen. The trap should not touch the parent hive. On the other hand, place a new hive at the side of the one the bees issue from; and as soon as the queen is seen in the trap, place it on the new hive and every bee will enter it and thus hive themselves. Release the queen when the bees begin to go in.

Wenham, Mass. Henry Alley.

[We sent the above to Mr. Pratt, who replies:]

All honor to Mr. Alley for inventing the first self-hiver! Even if he did not perfect it, great credit is due him for starting the thing. I admit that his first device caused me to take great interest in the matter, as it did bee-keepers all over the country.

Mr. Alley and myself *have* talked a good deal about self-hivers, and it was during some of those talks that I suggested the form and make of the box B connecting box A and C, which caused him to abandon the zinc tube used on his first device and adopt the improvements, although it was hard at first to convince him that the round connection was not the thing. Then after it was found *that* would not work I gave him the point of letting light into B B, over the cone, which proved a success in calling the queen into box B.

Mr. A. E. Boal's suggestion on page 706, Sept. 1, 1891, was the cause of box C being abandoned (see *Api.* for Nov., page 161), and the self-hiver illustrated by Mr. A. above was brought about in this way. Yes, Mr. Alley is perfectly justified in claiming his swarmer as all his own. I am pleased to receive suggestions that will help me perfect a device. It is in this way the most complicated machines are made perfect and useful.

I do not remember of Mr. Alley's telling me that he "did not know but that he should have to arrange the swarmer so as to compel the bees to pass *through* the new hive." If he did it made no impression on my mind. I do remember of his telling me that he would have to devise some way of compelling the bees to pass out of the hives opposite the entrance to the new hive, so that the queen would be trapped there, and more bees would pass in with her. I did not understand, as he has stated it, at all, nor did my new principle originate from any of Mr. Alley's statements. There *is* a little objection to having one hive placed before another, also beside another, and these objections I have overcome in a recent device with the new principle of trapping the queen in the hive the swarm is to occupy, and causing the bees to join her by the entrance they have become used to.

Mr. Alley is mistaken when he says my swarmer is an infringement upon his trap. Reading both patent claims will show that they in no way conflict with each other. One is used to hive a swarm of bees, while the other is used to catch drones. I can not but echo what Mr. Alley says about the advantage of his drone and queen trap, an excellent device. I have always been loud in its praise—justly too; but the drone and queen trap is not an *automatic* swarm-hiver. E. L. Pratt.

Beverly, Mass.

THE PRATT AUTOMATIC SWARMER.

ITS FEATURES RECONSIDERED BY C. H. DIBBERN.

I was very much interested in the Pratt self-hiver, as described on page 199 of Gleanings. I have experimented largely in that line during the past few years, with various devices of my own, with more or less success; but I am free to say that the Pratt is far ahead of any thing heretofore suggested. I am well aware that it is not very safe, usually, to give a positive indorsement to a device that we have not ourselves tried fully in actual use; but a single glance at the cut fully convinced me that the one great obstacle had been overcome. I had been watching for some further explanations from Mr. Dibble, who referred to some device of his described on page 92 of Gleanings, and still hope he will give us a description of his swarmer. I feel quite sure that the perfect swarmer will soon be produced, if, indeed, we have not already got it.

Let us consider some of the advantages of the Pratt over all other automatic hivers heretofore described. In the Pratt system the swarm returns to the same entrance to which they have long been accustomed, and, of course, there are no bees lost by trying to enter adjoining hives as is often the case where the queen is led to a new place. As the queen will be almost surely in front of the empty hive, where the bees will readily find her, it is quite certain that nearly all the swarm will remain in it with her. One great point in favor of this plan is, that the hives can remain safely as they are for a week or so, with advantage, as the young bees hatching in the old hive will be constantly reinforcing the new swarm. If the honey surplus cases are shifted over to the new hive, it will be a great help to them; and such a swarm should continue working in the sections right along.

Some of the disadvantages are, that the bees have to travel the whole length of the empty hive, passing two perforations before reaching their own hive. Now, if a queen-excluding honey-board is used, there will be a third perforation to be passed before the surplus cases are reached. This objection, however, may be more apparent than real, as that has proved to be the case with the queen-excluding honey-board. Another objection would be, that, in an out-apiary for instance, one could never tell when the bees had swarmed, without looking inside of all the empty hives. However, as dead drones will collect in the empty hives, they can be brushed off the bottoms by removing the hives, when, if there has been any swarming, it will be readily discovered.

I do not see that there is much less "machinery" about it than about most of the other self-hivers. It certainly will require nice adjustment to have all the parts fit nicely, and keep them in place so the queen will find no loophole through which she might escape. Another difficulty that will present itself will be that, in many hives, there is not room enough for the perforated bee-escape device for the bees to pass it readily under the frames. This can be overcome in a loose-bottomed hive by nailing narrow strips around the edges, or by slipping a narrow rim under the hive-body. In a tight bottom like the L. this is not so easy; and when you get the swarm hived in such a hive, one would have to take all the frames, bees and all, out, to get the device out of the hive. That would certainly be quite a job for a beginner. My own hives are admirably adapted to this system, as I have only to remove the back strip from the bottom-board. A hive, however, with a solid bottom, without an entrance in the rear end, and with insufficient space under the frames, would be difficult to arrange for this system.

But all these objections are as nothing when compared to the great difficulty which Mr. Pratt has overcome in preventing the greater part of the swarm from returning to the old hive. I shall certainly give this plan a thorough trial, and I am quite confident that it will fully solve a very perplexing question.

Milan, Ill., Apr. 4. C. H. Dibbern.

GRADING HONEY.

WHAT A CALIFORNIAN THINKS ABOUT IT.

Friend Root:—Having read with intense interest the many schemes of our eastern brethren in the bee-business, regarding the grading of comb honey, and not seeing any thing on the subject from the California bee-men, I thought I would say a few words to see if I could stir 'em up a little. As California produces considerable comb honey, I should like to hear something from her apiarists on this question of grading it.

For my part, I think there are too many grades proposed. We should put our honey on the market in such nice shape that the dealers would have to grade it as Pat did the whisky. Pat said the whisky was all good; and when pressed for a comparison, he admitted that some of it was a little better than others.

Now, on page 20, Gleanings, the North American says that combs so badly stained as to have the appearance of saffron should be thrown into grade M. I should say, throw them into the sun extractor. That would simplify matters a little. On page 22 a writer says that color and flavor should not be considered. The color of the honey is well enough, until it gets too dark, then it becomes sun-extractor grade; but flavor, I think, should be considered. The flavor is what sells the honey to the consumer. I have seen comb honey that looked as sweet and innocent as a sleeping babe; but one section of it was sufficient to break up the happiness of a whole family: the flavor was *bad*. Some thought the simple statement did not do it justice, and used more words to express themselves; but it was all in regard to the flavor.

On page 43 a writer says: "All combs containing much pollen, or that are badly travel-stained, or otherwise objectionable," (can he mean worse?) should be placed in grade M. Now, I think that, instead of having a grade for such honey, we had better have a class for such producers. I think that a bee-man who produces such comb honey should either revise his methods or be classed as an "old sock," and be set back about thirty years, where he could produce that good old-fashioned article called *strained* honey.

W. C. Frazier, on page 93, gives us the best plan of all so far. Now, if any one can make that any more simple, or shorten it in any way, he will be doing a real service. It comes pretty near the mark. But I should like to see it scaled down to two grades for market and one for the sun extractor; for instance, all the combs that were good enough so that the producer can put his name on them and guarantee them all right, should go as first-class; the second class should be honey that is good to eat, but not quite good-looking enough to go into the first class; should be sold on its merits for what it was worth; the rest should go into a nice warm sun extractor. But I want to say "kinder softly" to Bro. Frazier, that California produces considerable honey that would be classed as "Fancy A."

Some may say, "Oh! you bee-men away out there in great big California can make nice honey without any trouble; but it is different with us, as our seasons vary so." But, don't you believe it. If you were here you would get a chance every now and then to listen to a tale of woe from the California bee-keeper. If we could get the grading down so that two grades and a good sun extractor would do the business, it would be better for all hands.

Now, as I have dropped down rather hard on my friends in regard to pollen in the sections and travel-stained cappings, I want to say that, if your colony has a good queen and a proper hive there should be no pollen in the sections; and, again, if the sections are placed at the side of the brood, the cappings are very likely to be travel-stained; but if placed above the brood, and removed as soon as finished, they should be free from travel-stain. In working sections at the side of the brood-nest, the bees cluster on the sections nights and dull days, and that is what stains the cappings. A. B. MELLEN.

Acton, Cal., Feb. 27.

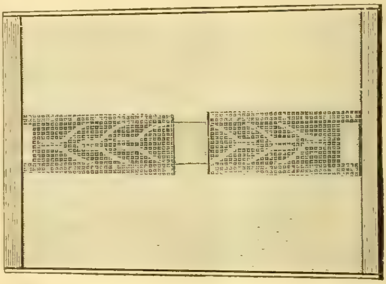
[We had decided, as announced in GLEANINGS, to call the discussion on "grading" at an end; but Dr. Miller protests, on the ground that the subject has not yet been sufficiently digested; perhaps he is right. We have concluded to reopen our columns for its further consideration, at least for one or two issues; and, besides, no one, till now, from California, the largest honey State in the Union, has taken hold of the subject, and that State should surely have a hearing, even at this late date. Yes, we should like to hear from more of 'em.

In our past discussions we have pulled the subject to pieces and viewed it piece by piece. Let us now come, as far as practicable, to a focus, and out of the several systems agree on one or at most two systems of grading. If further discussion will increase the number and variety of systems we had better stop where we are.]

THE COST OF PRODUCTION.

BEE-ESCAPES; BY J. H. LARRABEE.

As requested, I send you one of the bee-escapes that I have used for the past two seasons. It is not new in any point. I had seen Dibbern's, Reese's, and the old Porter, and decided to make some, as I had previously come to the conclusion that they were a success. You see, I had "tried it in my mind." I had on hand thin lumber of a certain width, and two of these widths were not wide enough for a whole board within about two inches; and as I laid the pieces upon an empty hive the idea occurred that this two-inch space was just what I wanted to put the escape in. The points about it that make it more effective than some of the other cone escapes I have seen are:



LARRABEE'S BEE-ESCAPE.

1. The three large cones are not easily clogged; 2. Plenty of ventilation to the super, thus preventing the excitement causing suffocation or gnawing of the cappings. The cost, you see, is almost nothing, and time in making it is about ten minutes. Like the new Porter or Dibbern's Little Giant it is a practical success. Brushing and shaking off bees is no longer done in freeing extracting supers; and when removing crates of sections the young bees are not crawling upon the honey-room floor or spotting the windows.

There is another subject upon which I wish to say a word. As you stated in your report of the Grand Rapids meeting, I made the assertion that I could care for 150 or 300 colonies, allowing half a day's labor to each colony, doing every thing from putting together of sections to crating the honey for market. As there was considerable discussion upon this point, and some seemed to think I had placed the estimate too low, perhaps it would be interesting to know how I would manage 150 colonies.

My bees are wintered out of doors in chaff hives, the brood-chambers of which are protected on top by a tray with cloth bottom, filled with chaff. On the first warm days of April I remove this tray, roll back the quilt, and see that each colony has a queen and stores. It is almost never necessary to remove a frame to ascertain either of these facts. If a queen is lacking I unite at evening, and if stores are lacking I remove one of the combs near the cluster and insert a frame of honey that I take care to have on hand. I am not stingy of honey, but see that they have enough to last till the harvest, and it takes lots of it at this time of the year. I go over the apiary in this way in a day. The next examination is made toward the first of May, when the tray of chaff is removed from the top of the frames and stored in a dry place, and the board cover placed on the brood-chamber. I keep an eye upon the condition of the bees at this time, to make sure that all have sufficient honey to last till the first of June. I also note any weak colonies for a little special care. At this time I slick up the apiary, remove and clean out combs and hives of colonies that may have died during winter, etc. This takes a couple of days more. About the middle of May I begin the business of preparing for the honey-harvest. In three weeks I have the foundation in sections, and in crates and frames in hives ready for swarms, though the work of preparing extra hives might be left out of the account, as no credit is given for value of increase. From the fifteenth of June to the twenty-fifth of July, my time is filled in with the work of the honey-harvest, putting on and removing sections, rearing queens, hiving swarms, and at morning and evening I find time to nail, paint, and repair, and bring up the odds and ends of work.

The most of my time after the fifteenth of July is devoted to preparing the honey for market; and along about the first of September another two weeks' work gets the average crop graded and into the shipping-crates. This gives me plenty of time remaining of the 75 days in which to prepare the bees for winter; and as they are in ten-frame hives, and have an abundance of good honey, this is not much of a job. The burlap covers and chaff crates I can put on in a day, and all is snug until next year.

It is by having a good convenient honey-house, an apiary of chaff hives, allowing plenty of room for good honey stores, and the practice of a definite system or plan of work, that I have done this. I am familiar with my hive, apparatus, and system, and there is something in this. We never have a fall honey-flow to a degree to make supers desirable.

In Pres. Taylor's estimate of cost of production, he allows only four dollars for the handling, from the hive to the honey-market, of each 1500 lbs. of honey. This seems to me too low. I should at least double it. For the New England markets, the sections must all be scraped, and the honey carefully graded and packed in crates with glass or in cartons, and neatly stenciled and marked, and this is necessary in order to get the 15 cents per pound of Mr. Taylor's estimate.

I believe that the most economical method of running an out-apiary is to cage the queen to prevent swarming. This seems as yet to be the only practical method unless some one watches for swarms. It is nice to run the out-apiary for extracted honey, and discouraging swarming by plenty of room. I understand that our friend Manum has secured the past season a good crop of comb honey from several apiaries, almost alone, on the caging plan. I am also looking with much interest for the article from friend Hilton upon this subject of cost of production. As I spent several days with Mr. H. after the State convention I had the opportunity of observing that he was careful and systematic, and that his methods were very similar to mine—so much so that he remarked we could not get into an argument.

J. H. LARRABEE.

Ag'l College, Mich., Jan. 20.

[We may explain, for the benefit of our readers, that our first knowledge of the Larrabee bee-escape came while we were in attendance at the convention of the Mich. State B. K. A. at Grand Rapids. When Mr. Larrabee explained the principle of it we were interested; and when he told us that his brother took off 3000 lbs. of extracted honey without so much as brushing a bee off the combs, we were elated. As you will remember, we asked one of the Larrabee boys to send us one of their escape-boards. They did so, and the engraving above illustrates somewhat the principle. We might add, that it is simply two boards cleated around on the sides, leaving a bee-space on one side. The boards are left about two inches apart, and on two sides are nailed strips of wire cloth, covering the opening as shown, the strips being of unequal length. Between the strips are two sets of three horizontal cones of wire cloth pointing in opposite directions as shown. The fact that bees have got to go through three cones is pretty good evidence that it would be quite unlikely for them to get back into the super; and then, the ventilation is perfect. As to whether the Larrabee escape will work as well as or better than the Porter remains to be proven. As Mr. L. says, it combines the old principles of the Reese and Dibbern escapes; but it seems to us in a very unique and practical manner.

In regard to the cost of honey, we regarded Mr. Larrabee's statement as being very conservative and fair. He uses in Vermont the large chaff hive, and these stand out both winter and summer, and they require but very little labor. That is one beauty in having chaff hives. They cost a little more, but they save a great deal of labor in springing and wintering in the way of moving in and out of the cellar and in hauling. There are some localities that are too cold for outdoor wintering of any kind, at least we are so informed; and for migratory bee-keeping or for any reason that the hives must be moved often, the chaff hive is undesirable. Our small Dovetailed chaff hive is an exception. It is but a trifle heavier than the single-walled hives, and is equally portable.]

PREVENTING PROPOLIS AND BURR-COMBS.

TALLOW AND VASELINE FOR THE PURPOSE.

I want some advice and help. We have been told for many years, that, if we rubbed tallow on the joints of our hives and other places where we did not want propolis to accumulate, the bees would not put it there. Now, I want to know whether there is any one who has tried it on a scale large enough to know whether it is practical or not. Some Englishman, I believe, has lately been recommending vaseline for the same purpose. Who has tried this? Does either of them, or any thing else, prevent propolis enough to make it profitable to use? It would be worth something to get rid of propolis where it is not wanted. It is for another purpose, though, that I think it might prove profitable to use the plan; that is, in the prevention of burr-combs.

Several years ago I made some frames to hold cages in which to put queen-cells for hatching in the hive. Wishing to have them as perfectly movable as possible, I rubbed them well with tallow. They have always been used in hives where all the other frames were covered with burr-combs; but on these no burr-combs have ever been built. I am certain from this that burr-combs might be prevented, at least to a very great extent, by rubbing the top-bars with tallow. It is possible that the bees might object to its use on a large scale, or it might lose its efficacy in time. I should be glad to have testimony on these points from any who have tried it enough to know. Vaseline, it seems to me, would be more apt to be objectionable to the bees. It would also cost more, though it would be easier to apply.

USING KEROSENE TO STOP ROBBING.

Some one has advised the use of vaseline, rubbing it on the alighting-board of the colony being robbed. A handier and cheaper thing to use for this purpose is kerosene. In robbing, as with all other evils, prevention is better than cure; but it will sometimes happen in all apiaries that the bees get to robbing. If the robbed colony is at all inclined to defend its hive, a simple contraction of the entrance, or almost any of the ordinary methods, may be sufficient; but often the robbed colony gives up completely, and makes no effort to keep the robbers from entering. In such cases, something must be done to take the place of their lost courage for a time. For this I have found kerosene very effectual, pouring a little of it on the alighting-board and around the entrance. Through this the robbers inside will pass out, but those returning will seldom make any attempt to enter. If any of the bees of the colony are out, they will usually go in all right after a little time, because it is their *home;* but the robbers do not.

It is best to contract the entrance, and in bad cases it may be well to renew the application after a time. Generally this is not necessary, and this feature makes the plan particularly valuable at an out-apiary, where one has not time to wait to see how a case of robbing is coming out, and does not wish to leave a colony with a too contracted entrance. At such a time the entrance may be somewhat obstructed with fresh grass, and kerosene sprinkled on this, and the colony left with confidence that it will come out all right, if it is not queenless or too weak to hold its own.

THE PORTER BEE-ESCAPE.

Those Canadians who are rumored to have decided against the Porter bee-escape on the ground that it tore the wings of the bees must certainly be mistaken. Some one has probably seen the old ragged-winged workers, which are to be found in all hives during the working season, and jumped at the conclusion that their wings had been torn by the springs of the escape. I have used a number of these escapes, and I never saw any thing of the kind, and I do not believe it possible.

PROPOLIZING PERFORATED ZINC.

I see that some of your correspondents have been troubled by the bees closing the perforations in queen-excluding zinc with propolis. Without knowing more of the facts it is impossible to say certainly why this should be so; but in all probability too much ventilation through the top of the hive is the cause. I have frequently known bees to close in this way the holes in the top of box hives that were intended to give entrance to the surplus apartment. I have also often known bees to use much labor and propolis in contracting an entrance that was too large to suit them. They would not use this at the entrance, though, where a comparatively small quantity would have sufficed, but attempted to build a wall with it some distance back, usually between the lower corners of the frames. It is generally only small colonies that do this, and their evident purpose is to shut out the drafts in order to better preserve the heat of the hive.

As long as the perforated zinc is used for its legitimate purpose as a division between the brood-chamber and the surplus apartment, the holes are not likely to be propolized; but when the bees are not occupying the supers, and the honey-board becomes practically the cover to the brood-chamber, their instinct leads them to close the openings in it if possible, especially if there is a large open space above, through which the air can circulate freely.

When the bees are not occupying the supers, the honey-board should be covered with a tight board, held a bee-space above the zinc, or it should be removed, and a board or cloth put in its place. J. A. GREEN.

Dayton, Ill.

RAISING QUEENS IN HIVES ALREADY CONTAINING A QUEEN.

DR. MILLER ANSWERS QUESTIONS.

This letter is anonymous; but there is no evidence that it is meant in any but good faith, and the subject is an interesting one and may be useful to others.

Dr. C. C. Miller: Will you please answer the following questions through GLEANINGS?

On page 333, 1890, you mention a way to have cells built by the bees, and have the queen fertilized when hatched. You say, " Let there be an entrance on top." Now, what I want to know is, if I do not make an entrance on top, but only the original entrance at bottom, can I raise cells, the cells to be cut out a few days before they hatch, and given to full colonies, as I wish to requeen all my hives? My bees are black, and show some trace of Italian stock, which I wish to get rid of and come back to the original black stock that I had years ago when I used to get honey. I used to raise what queens I wanted, by the nucleus system; but if I can raise them in full colonies without having the hives queenless, I think it would be better. The system you recommend seems to me to be really two distinct colonies. If I do not let them have two entrances, will the bees below go above and raise cells and really act as one colony?

A SUBSCRIBER TO GLEANINGS.

Yes, you can raise cells just as well without any entrance above, if you want to cut out the cells before they hatch. I think you may find the plan to succeed well sometimes and sometimes to fail. The first time I raised any cells in the way mentioned was in a hive over which I had placed three stories of empty combs to be taken care of by the bees. In order to make sure that the bees would traverse the entire lot, I put a frame of brood in the upper story. There was no queen-excluder, and nothing to hinder the two queens coming together except the fact that they were so far apart that it was easier for the young queen to use as an entrance the hole she found accidentally left above. This case was reported in GLEANINGS at the time, and I think it was the first case of the kind ever published.

No, there are not two colonies. I don't know just how much separation is needed, but it seems that, whenever there is young brood to be taken care of, and the queen does not have ready access to it, a certain amount of isolation will induce the bees to rear queen-cells, even if there is constant communication between the bees of the two parts.

I have not always succeeded in getting the bees to raise cells in a second story with an excluder between. But I'll give you a plan for raising cells that may almost always be depended upon, and you need no queen-excluder. Instead of a queen-excluder, put between the upper and lower story a quilt or sheet; if holes are torn in it, no matter. But there must be some place, at back, front, or side, for the bees to pass up through, and I don't know that it makes much difference whether a square inch is left for a passage, or ten inches. The point seems to be, that the cloth cuts off direct communication between the two stories better than the queen-excluder. If very much of an opening be left, the queen will sometimes go up into the upper story, especially if she hasn't all the room she wants below. Of course, when she goes up, the cells above will be destroyed, unless there is some intention to swarm; but in any case the bees will start cells below. So I have often left the colony in the upper story, and put only one comb of brood in the lower story, to find cells almost surely started below.

Now, some one will say that this is a good plan to have queens renewed—simply let the young queen hatch out and kill the old one. I've had no trouble in having the young queen hatch out, but in a few days she was always missing, and the old queen serenely maintained supremacy. With an excluder between, and an entrance for each queen, the case might be different.

You want to get rid of the trace of Italian blood. I wish I could swap for it the trace of black blood in some of my colonies, and have as pure Italians as some I had "years ago, when I used to get honey." But I'm afraid that, if you had the same pure blacks back, you'd find that they wouldn't give you a crop without a good season. We've had bad seasons lately. It is quite true that Italians have not secured crops; but I have no distinct recollection of reading about the blacks storing better crops than the Italians. C. C. MILLER.

Marengo, Ill., Mar. 17.

REPLIES TO INQUIRIES.

WEIGHT OF COLONIES.

Question.—What becomes of the difference between fall and spring weight of colonies, sometimes amounting to 20 to 25 pounds?

Answer.—Bees use honey largely as fuel during the winter season, in order that they may not freeze during the frigid weather of our northern localities. The natural food of the honey-bee contains the least possible amount of gross matter; and as bees do not take on fat and thereby increase in weight, the digestion of honey in the stomach of the bee is equivalent to combustion; or, in other words, the honey is burned up; hence as the ashes of burned fuel do not weigh anywhere near as much as the fuel did before burning, so the "ashes," or what is left in the intestines of the bees, weighs much less than did the honey consumed to keep up the fire. Again, much of the weight of the hive goes out by evaporation; and should the bees have a flight, more would go out by way of excrement, but not nearly as much by the latter as by the former. Honey being very free from nitrogenous matter, it is passed off in liquid or vaporous form by way of sensible and insensible perspiration and respiration, except the small amount to be found in the bodies of the bees. This is sometimes carried on to such an extent that water is often seen running out at the entrance of hives in winter. Some of the food is also used in producing muscular force; and as this force is constantly wearing out, the loss is perceptible in the food, while in the weight of the bees it is not seen. In all of the above we see the wisdom of Him who created our pets; for were it otherwise they could not stand the rigors of our northern latitudes at all, inasmuch as they are too cleanly to soil their hives, while the weather will not admit of their leaving them, often, for months in succession.

FEEDING BEES IN WINTER AND SPRING.

Question.—What is the best method of feeding a colony of bees that is found to be without food in the hive in midwinter or early spring?

Answer.—In the first place we should never allow our bees to be in this condition, for it is much more to our advantage, and to the advantage of the bees, to have sufficient food supplied them in the fall to last at least till the last month of spring, and I often think that, if enough is given to last till June it is all the better. The prudent apiarist will look over all his colonies in October, and see that *all* are abundantly supplied till the flowers bloom again. However, should such a thing as our pets being short of stores happen, through sickness or other adverse circumstances, the very best method of feeding them is to set in combs of sealed honey, as this places the bees in a natural condition and does not disturb them every little while, as most other modes of feeding do. If no combs of honey can be had, the next best way is to fill combs with good thick sugar syrup, when they are to be used in the same way the combs of sealed honey would be. In either case such combs of feed should be warmed for six hours or more before being placed in the hives; for, where combs of frozen honey are set next the bees, the colony is thrown into a state of excitement to warm this honey up to where they can safely cluster against it.

There is still another way of feeding which I like very well, especially if this feeding is done in the spring, and where I have on hand some extracted honey which has candied, which is as follows: Make a bag out of cheese-cloth, about six or eight inches square, or that much in diameter, after which partially fill it with the candied honey, which has previously been worked till it is quite soft, or it can be worked after it is placed in the bag. Don't fill the bag so but that it will assume a flat shape, for we wish to press it down right over the cluster of bees, so it can be covered over snugly with bee-quilts or old carpeting to keep in the heat. The bees will suck the feed through, and in process of time cut through the cloth so as to use it all up.

LOCATING AN APIARY.

Question.—Which is the better location for bees—one on low ground, where it is moist and frosty in the spring, but sheltered, or one on high ground, where it is free from dampness, but somewhat windy?

Answer.—If I could have my choice I would select neither. My choice would be midway on a moderate slope which faces the southeast. This would avoid the early spring frosts and the dampness of the low lands, and, to a large extent, the high winds of the elevated position, which are almost sure to prevail. To be sure, a windbreak can be constructed around the apiary on the high ground; but according to my experience, many bees are lost by being swept away on windy days upon rising above this inclosure into the cold blasts which blow about it, they being allured out by the calm and sunshine within. For this reason I would select the low ground in preference to the high, had I not the privilege of taking the intermediate one. If bees go out from the warmth caused by the mid-day sun shining in this low ground, they are not liable to be lost thereby; for when they rise high enough to strike the cold air from above they at once fall into the warm air below, so are not lost; then on the whole the temperature at the low location will average the warmest in early spring. G. M. DOOLITTLE.

Borodino, N. Y., Apr. 1.

TABULATED REPORT FROM FLORIDA.

THE HONEY RESOURCES OF THAT STATE.

I herewith send you my second annual report of the bee-keeping industry of our State. I have arranged it in a tabulated form for compactness and convenience. I have spent no little time and money in preparing the report, and have tried to have it as complete as

NAME AND ADDRESS.	Col's at date	Kind of Hive used.	Incr'se, % of	Plants from which the Honey mostly was taken.	Average Length of the Honey Season.	% of crop.	Lbs. of C H'y.	Lbs. of Extr'd.	Lbs. of Wax.
John Craycraft, Aster Park	20	Short L., 10 f.	—	Orange, palmetto, button-bush, grape.	March—July.	25	—	500	0
John Cross, Arcadia	35	Simplicity.	100	Palmetto, pennyroyal, oaks, etc.	February—May.	85	—	—	
J. B LaMontagne, Winter Park	24	Crosswise L.	50	Orange, palmetto, goldenrod.	Mar.—July; fall.	30	—	240	0
H. P. Williams, Richmond	13	Frame.	50	Orange.	Febru'y—March	50	—	—	—
A. W. Windhorst, Valrico	6	New Heddon	50	Orange, palmetto.	February—June.	75	150	100	5
Lewis James, Rock Bluff	75	Box.	50	No report.	May—June 30.	50	400	900	200

possible; but owing to many of the friends not answering all the questions it is rather hard to summarize it as a whole. I sent out some 500 printed blanks on postal cards; but with this convenience only about one-fifth of the friends replied; and this, too, when I know from private letters that a good many of them had secured very fair crops. From information thus gained I estimate the number of colonies in the State at about 12,000 and the honey crop at 500,000 lbs. for the past year. On the Apalachicola River there are over 3000 colonies not listed in the report, and these men have all secured from 60 to 90 per cent of a full crop. I have not tested them, for the reason I have not received personal reports from each, only an estimate from one or two in each district.

In summing up the report we find: 1. That 110 persons report a total of 5305 colonies, an average of about 48 colonies to each; 2. That 37 per cent of the bee-keepers use the Simplicity hive; 28 per cent the Langstroth; 16 per cent box hives and 30 per cent miscellaneous makes; 3 That 86 report on increase an average of 56 per cent; 4. That the main surplus honey comes from orange, gallberry, tyty, tupelo, snowvine, black gum, saw and cabbage palmetto, black mangrove, pennyroyal, goldenrod, and partridge pea; 5. That there is surplus during nealy every month in the year in some locations, and that we can take two or more crops during a year by moving our colonies to such locations; 6. That 66 report that an average of 56 per cent of a full crop was secured by them; 7. 76 report from 4402 colonies 13,540 pounds of comb and 180,543 pounds of extracted honey, making a total of 194,043 pounds, or an average of about 44 pounds to the colony; 8. 48 report 2669 lbs. of wax; 9. (not in report), that from 500 blanks sent out to the bee-keepers of our State I have been able to obtain only 110 responses, as given above.

Hoping the above report will be of some value to you, my friends, the coming season, and that I may again hear from you, I am your obedient servant, A. F. Brown.

Huntington, Fla., Feb. 21.

[Perhaps some of our readers may think we are giving a good deal of space for the statistics of one State. However that may be, we give the room in order to show how the work may be done, and to give a better idea of the real honey resources of Florida. While we may not be able in the future to publish these State statistics in full, we shall be glad to publish the summaries giving the gist of the whole matter. We hope, therefore, that other States will follow suit. If California bee-keepers would get up statistics as complete as these, we should be glad to publish the entire report, even if it took several pages. Such a report would be valuable, coming from the greatest honey region of the world.]

PAINT FOR BEE-HIVES.

THE BEST PAINT; PRIMING COATS; HOW TO DETECT ADULTERATION IN PAINT, ETC.

By Ernest R. Root.

We have already given some hints in regard to the most durable paint for bee-hives; but during the last few months we have been collecting material from various sources, and are now in position to offer some information that may be valuable to our readers, now that we are about to enter upon spring weather, when the bee-keeper may have time to paint some of his hives that may be sadly in need of it.

It is a well-known fact among painters, that yellow French ocher gives a very permanent covering, especially for priming coats. Ocher would doubtless supersede even white lead were it not that its color is against it. It is also stated that a priming coat of ocher presents such a hard surface that a covering of lead does not adhere so well as it does to a priming coat of lead. A few years ago nearly all the priming was done with yellow ocher; but it was discovered that the later coats of lead would flake off; so generally, now, for house-painting, pure lead for a priming coat is preferred, providing it can be obtained. But we shall have occasion to speak of adulterated leads further on. It is generally acknowledged that French ocher combines very readily with lead, and the combination makes a more durable paint than even pure lead; but, unfortunately, so-called pure leads are fearfully adulterated. Dealers get to cutting on prices, and manufacturers are tempted to put in barytes, lime, and other cheap ingredients, which, instead of adding to the permanence of the paint, work in an inverse ratio. The result is, that some of these adulterated lead paints show a very poor surface in a couple of years. The paint either flakes off or rubs off like chalk.

Besides pure lead, and genuine yellow French ocher, pure zinc is another good body for paint. The addition of zinc—at least a small proportion does not generally affect the durable qualities of paint. Pure zinc paint alone gives a very hard, snow-white, porcelain finish. For inside white it is generally employed; but for outside work it is too hard and flakes off. Our painters, however, tell us that, while pure lead and pure ocher give a most lasting combination, the paint may be cheapened by the addition of a little zinc; and this will, at the same time, give it a valuable quality in point of hardness, and prevent inclination toward chalking off. We are now using on our hives a combination made up as follows: ⅓ pure lead, ⅓ pure zinc, ⅓ genuine French ocher, mixed in pure unboiled or raw linseed oil. Such a combination is cheaper than a great many of the so-called mixed paints on the market—cheaper because it goes further, and because it will last much longer. It has all the valuable qualities of the zinc, the ocher, and the lead; and the resultant shade is a light straw color. For bee-hives it is undesirable, on account of melting down the combs from the sun's heat, to use dark shades. Theoretically, snow-white paint would be preferable; but in actual practice the light straw yellow will do about as well as the white.

Now a word about buying paints. It is to be regretted that so many manufacturers of white paint label their paint "Strictly Pure." If you consult any practical painter he will put you in possession of tables containing analyses of all the paints in the market—analyses that show the amount of adulteration and pure lead sent out by each manufacturer. If dealers and consumers alike could only understand that pure lead, or pure lead and zinc, is a great deal cheaper in the long run, they would not try to be buying their paint wherever they could do so for the lowest figure. It is the consumers who have to suffer, and some cheap paints are very dear at any price.

Besides the adulterations which do not in the least add to the good quality of paint, fish and mineral oils are used instead of pure linseed oil. Painters generally agree that there is nothing like pure linseed oil for paint. All other oils are practically worse than nothing. They are a snare and a delusion, and only reveal the true nature of the paint after it has been on the wood for a few months.

Very fortunately there is a simple way of detecting adulterations in paint. Any thing but linseed oil can usually be detected by the smell. Fish oil has a very rank, sickening odor. Barytes and lime can usually be detected in the following way: Buy a small can of the lead that you propose using with your ocher or zinc, as the case may be. Scoop out a little of it and put it in an empty tin can; pour on top turpentine. Mix thoroughly by stirring, and then allow this to stand for 24 or 48 hours. At the expiration of this time, pour off the top; and if barytes or lime is used you will find a sort of dry powder in the bottom of the can, that has failed to unite with the oil. This lime or barytes is a positive detriment; and the only reason it is put in is because it cheapens the lead. If, on the other hand, after making the test as above, you find no chalky residue in the bottom of the can, you may feel pretty sure that your lead is pure, or, at least, has nothing worse in it than an addition of zinc, which will not hurt it. Genuine French ocher, on the other hand, combines perfectly with the lead or zinc, and leaves no residue.

There is another very simple test, though perhaps not so positive in its results. Dip your thumb and finger into pure white-lead paste and rub them vigorously together for four or five minutes. If the paint is made of pure lead and linseed oil, or of pure lead, ocher, and linseed oil, a rubbing of the fingers for four or five minutes will still leave only a soft oily residue. If, on the other hand, the paint is adulterated with barytes or lime, two or three minutes' rubbing will reveal a sort of dry powder between the thumb and finger. Linseed oil combines perfectly with lead, zinc, and ocher, but it will not combine with lime, barytes, or chalk, and hence the fraud is easily detected.

Perhaps we might state, while we are about it, that there are on the market what are called white and gray ochers. We would warn bee-beepers to let these alone. The only reason they are called "ocher" is because the general public understand that ocher paints—at least the yellow ocher—is known to be durable when spread upon the wood. We have tested some white ochers; and while we could not tell exactly, we felt pretty sure they were made up of barytes, lime, and clay. Gray ocher is, perhaps, a little better; but it does not begin to have the qualities of the yellow ocher.

While we are about it, we might add that Venetian red also makes another durable body when combined with pure linseed oil. Its color, however, is against it. You can get a very pretty and durable red by mixing pure French ocher and Venetian red, half and half. Such a red will not deteriorate into a dull brownish red, but will remain of a bright glossy color. We use such a paint on our outside winter cases, or on any thing that is not to be used for summer use. We also use it on hive-stands. The bright-red hive-stands and the straw color of the hives make a very pretty combination in an apiary.

It may be also stated that dark shades are apt to burn off more by the effect of the sun than the lighter shades.

We have thought best to make some extracts from the readings we have made. They not only confirm in some cases what we have said, but they will be found to give other additional facts.

IMPORTANCE OF GOOD PAINT.

We are probably more indebted to paint than to any other article for the preservation of surfaces that are exposed to the elements; and it is therefore desirable to use only the best. Notwithstanding the experiments and trials that have been made with other materials, thus far nothing has been found to take the place of white lead (carbonate of lead) and linseed oil. Owing to the high cost of these articles other metals have been repeatedly tried, and even more extended experiments have been made to substitute some other oil for linseed, but without success, and they still hold their supremacy for painting purposes. The carbonate of lead contains, in addition to the metallic lead, a certain percentage of carbon and oxygen, and just sufficient hydrogen to give it the proper spreading quality. Linseed oil also contains carbon, oxygen, and hydrogen, and hence its affinity for the lead, causing the two to unite perfectly. The natural formation of carbonate of lead, however, is such that it has a tendency to chalk off; and the more advanced authorities in paints employ the use of zinc oxide to correct this tendency; and experience has proven that this combination of lead and zinc insures a more durable paint than lead alone.

As white paint is more subject to being soiled from dust, smoke, etc. (the favorite painting materials are in colors), the most durable colors are the iron oxides; but these are usually too dark in color to be pleasing to the eye. Chromates of lead, i. e., yellow and green, are used largely in varying tints and shades. Combinations of different pigments are used in almost endless variations. Probably there is no color that is more of a favorite, however, than ocher; and as it combines perfectly with white lead, it makes a good paint. Ocher is a substance, the best grades of which are found in France. It is composed of alumina, silica, and hydrated oxide of iron. From the latter it obtains its peculiar rich yellow color. Many pleasing tints are made by combining ocher with white lead; and although it may not perhaps be indorsed by the æsthetic as the color "par excellence," it is always a reliable and favorite color, and is more largely used than any other color of its class.—*From the Forest City Paint Co., Cleveland, Ohio.*

THE PRIMING COAT.

Many painters do not give much attention to this most important of all coats. They seem to think and act as if any thing were good enough for a primer. We have frequently seen odds and ends in the slush-tub furnish the material for priming; and if for any reason a lot of paint is condemned as unfit for finishing coats, it is reserved and thought to be good enough for first coat.

It is, however, of the utmost importance that the priming receive the greatest attention and care, as, if it is neglected, the whole superadded coats are bound to be defective. It matters little how good these may be, nor how careful the workmanship; there can not but be trouble in view in the near future.

Wood, it will be noticed, is composed of bundles of thread-like filaments; where these filaments have been sawed through, they present the appearance of pores. Under microscopic examination it will be found that there is considerable space between the filaments, and that they are not solidly laid against one another. These interstices it is that the primer is called upon to fill. The primer will be found to have little bits of roots, which form clinchers. These clinchers have a great hold upon the wood, and it is of the utmost importance that both the pigment and the vehicle be of the best quality and of the proper nature.

The vehicle should be raw linseed oil, for this penetrates much further than the boiled will, and for that reason the latter should not be employed.

Earth colors containing considerable silica which have been very finely ground are the most useful pigments for priming, and the ochers for that reason are the best of all these. They contain considerable silica, and have great body besides. The addition of a quarter to a third by weight of white lead is an improvement, as the paint is then more porous and the next coat can penetrate through it.

Never use a dry ocher unground for priming, as the particles are much too coarse and can not enter into the pores. Have only careful, reliable men to apply it, as it must be thoroughly brushed in to get well worked in, and we know that there is no class of work that is slighted more than this is in the workmanship. Any thing in the shape of paint, and anybody to put it on, won't do.

Zinc should never be used in priming, for the reason that the tendency of zinc is to peel off; and we have frequently seen it do so where it had been used as a primer; even the rootlets formed by the entering of the primer into the pores are drawn out from this. For this reason, then, zinc should be discarded altogether for a primer.

Too great a body is not desirable in a primer; and, while both the ochers and white lead are heavy bodied, they must be thinned down with the vehicle until they are very thin. *F. Maire, in House Painting and Decorating.*

In mixing car colors of a light shade, or straw colors, we find that a pure white lead is first necessary, which should be tinted with the best French ocher and English chrome yellow. This will make the most durable color for car bodies; the chrome is permanent when mixed with lead almost as much so as the best ochers; but it is far superior in body and covering properties, and one of the most useful pigments in the paint-shop. White lead alone will change from its original whiteness in case it is mixed with a surplus of oil; it is the oil which changes it to a yellow cast as it hardens in drying; but when lead is mixed with some other strong pigment, its color when thus tinted is more permanent, and its density and wearing qualities are increased. The durability of a color we do not claim to be altogether in the pigment employed, but it is equally so in the vehicles used in its preparation for use; therefore lead, which is known to retain oil the best, will hold the color longer.

Painting is put to the severest test on our passenger cars, and its destruction is caused by a constant exposure to the elements and the changes of atmosphere, from a dry, burning heat through the day to a heavy moisture at night, which the painted surface absorbs in large quantities, to be dried out again, the same process going on day after day. But perhaps it is, as I have heard expressed by members, that the foreman painter is not consulted in regard to the color of the car. This is generally decided by those who know nothing of the general adaptability of a paint to the work. Freaks of fancy have too often determined what the color of the car should be, with no thought given or questions asked of those who are expected to know the difference in the lasting qualities of a color, nor is the question considered whether the color would wear six or twelve months. Would it not, therefore, be economy to ascertain what amount of wear is in a color before it is finally adopted as the standard of the road?

Our arguments in favor of the light colors will probably not change the views of the officers of our roads. They may, however, find the matter worthy of their attention, and, to test it for themselves, have one coach painted any light shade, and put it in service with a car painted Pullman color or Tuscan red, when twelve months' service will prove what I have already asserted, that light colors are the first step toward economy in the car-painting department of a road. *R. McKeon, in The Painter, for Nov., 1884.*

After complaining what others have said about *honey* being adulterated, it might look as if we were going a little fast when we intimate that *paint* is also. Prof. Cook has said, and no doubt correctly, that it is almost impossible to tell by analysis whether honey is adulterated or not. In fact, he sent samples of pure honey, taken from the hives of the college apiary, to Prof. Wiley, of Washington. Prof. Wiley, after analysis, pronounced them all adulterated. The wily professor no doubt thought that they were, *of course*, adulterated or they wouldn't have been sent; and when he saw the expected chemical reactions, he jumped to the conclusion that the samples were necessarily impure. Fortunately, adulterations in paint are very easily detected. We have given two very simple methods that will answer for the practical bee-keeper or painter; but the chemist can analyze and determine the exact amount of each foreign article in paint to a certainty. All minerals are very easily analyzed, and the chemical reactions are distinct and positive.

Perhaps we ought to say that we are largely indebted to our painter, Mr. John Iper, of this place, for the information that we have been enabled to give above. It was he also who furnished us the articles from his trade-journals, from which we made selections.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

DEATH OF COUNT C. BIANCONCINI.

It is with much regret that we chronicle the death of Chas. Bianconcini. We copy the following short sketch from the *British Bee Journal* for March 17:

> With Italy we have also to deplore the loss by death of Count Charles Bianconcini, of Bologna, whose name is well known the world over as one of the leading queen-breeders of Italy. Count Bianconcini was brought up as an engineer, and served his country in the artillery, from which he retired with the rank of captain. He was not only passionately fond of bee-keeping, but was also a thorough gentleman, and his strict integrity won for him the esteem of all who knew him or had any business transactions with him. In his business dealings he was most honorable and obliging, and those who have had dealings with him have always spoken in the highest praise of his queens. Foul brood does not exist in the district where Count Bianconcini resided, therefore there was no fear of importing this disease with queens sent from his apiary. He was also equally well known as an agriculturist. Our relations with him have been of the pleasantest; and the editor of the *Revue Internationale*, writing about him, says that, after fifteen years of the most agreeable intercourse, he can affirm that not one of his immense circle of customers has had to complain about him. His loss will be sorely felt in Italy, where his reputation was as good as it was abroad.

[For the last six or eight years we bought all our queens from Italy of Bianconcini. They were uniformly good, and gave excellent satisfaction to our customers. His business relations with us were also of the pleasantest; and as a bee-keeper and queen-breeder he stood high. We are happy to announce that his business will be carried on by his daughter, Miss E. Bianconcini, Bologna, Italy. She no doubt has been her father's best assistant in the apiary, and will therefore be fully able to sustain the reputation of her father. We expect to give her our patronage, and would respectfully refer others to her.] E. R. R.

POISONOUS HONEY.

I have a young man living with me who has lived all his life in northeast Tennessee. He says every one keeps bees there; besides, the woods are full of wild bees, but he never saw a bee on what is called mountain laurel there, and he don't believe they can work on it on account of the sticky nature of the blossoms; but they *do* work, in times of scarcity, on a small evergreen shrub called ivy in his locality, (may it not be confounded with the laurel in some other locality, as happens with other plants?) and what honey they store while it is in bloom is dangerous. He has been very sick from eating it, and knows a number of other cases, and one child died. The bees never seemed to do well when they had any of this honey in their stores. The symptoms of poison, as he gives them, are similar to those given by Dr. Grammer, in the A B C.

I looked through my apiary yesterday. The Italians (Root's and Nebel's stock) are in fine shape—lots of bees and stores, and a good bit of brood; but the blacks are in rather poor shape; did not feed up well last fall. Give me Italians every time. They are the "hustlers."

Parker, Kan., Mar. 29. J. W. GROVE.

A LETTER FROM CUBA.

Friend Ernest:—I notice in GLEANINGS of Feb. 1st that you think your father is coming to Florida, and might *possibly* come to Cuba. Well, we Cubans will just be delighted if he will consent to come—I mean the bee-keeping fraternity. This is not only a honey country, but a mass of flowery vegetation, with sugar-plantations, miles wide, dotted here and there with enormous sugar-factories, and the climate is just delightful from October until May. The place to take the boat would be at Tampa, Fla., there being a line of elegant steamers that run from Tampa to Havana, a distance of 320 miles. The run is made in about 24 hours, with a small stop at the charming city of Key West, Fla., which has a population of about 20,000. It would be best to write to Dr. James Warner, Havana, about three days before your father takes the boat at Tampa, so as to meet him at the boat-landing in Havana, for every one speaks Spanish, and possibly he might be annoyed. Dr. Warner lives in Havana, and is quite an extensive bee-keeper. Mr. Casanova is living here, and he is a fond lover of bees, and, besides, owns one of the finest sugar-plantations in Cuba, as well as a fine new sugar-factory, and he too would be very glad to have the honor of entertaining Mr. Root. With the hope that we Cuban bee-keepers will be honored by Mr. Root's visit to our land of palms,

I am sincerely yours,
F. O. Somerford.

San Miguel, Cuba, Feb. 14.

[Many thanks, friend S., for your very kind invitation; but, as I have before explained, you will have to wait until some future time before we make that pleasant visit. I assure you that your kind invitation has done us both a great deal of good. The fact of having such friends away off in Cuba is of itself worth a good deal.] A. I. R.

PORTER'S BEE-ESCAPES ARE A GREAT SUCCESS.

In an editorial in Gleanings of March 1, the editor asks any one in a position to know, whether the rumor that he heard was true, that a Canadian association of bee-keepers condemned the Porter bee-escapes, saying that they tore the wings of the bees. No; that rumor has no foundation whatever, and no Canadian association of bee-keepers did or could be got to condemn the Porter bee-escapes, because, wherever any bee-keeper in Canada has tried the Porter escape, he speaks of them with unlimited praise. If any one will tear one of the Porter escapes open and examine it he will be convinced at once that they could not in any way injure a single bee. No bee-keeper on this orb of ours should be without more or less of Porter's very valuable escapes. They are one of the best things ever brought into any apiary, and they should be used in every bee-yard in the whole wide world.

Wm. McEvoy, *Foul-brood Inspector*.

Woodburn, Ont., Can., Mar. 14.

A SUGGESTION.

To meet the objection of Mr. Walrath, to V'ing the sides of the end-bars of the Hoffman frame why not make the V by cutting the wood away all on the outside thus:

This leaves the inside next to the bees smooth. But the frames would have to be all square and close-fitting in the hive; *i. e.*, have no end play, else the sharp edge of the end-bar would not always touch its adjoining bar. Perhaps by leaving the point of the V $\frac{1}{16}$ inch thick would make it work. E. H. Whitaker.

LaSalle, Ill., Feb. 24.

[Your sharp edges would be impracticable for the very reason that in practice it is impossible to avoid all end play; and when there is end play, the sharp edges would slide by the square edge, and thus destroy the function of accurate spacing. Even if the hives and frames are made ever so nice, moist and dry weather would make it impossible to get the frames down in the rabbets.]

SEVERE WINTER LOSSES; CONDITION OF MY BEES.

The honey-dew is doing its best in this part of Uncle Sam's domain. When I go down into my bee-cellar the odor is dreadful; the floor (made of cement), barrels, boxes, shelves, every thing, are covered with dead bees, and soiled. Over half of them are dead; the other half, or one-third left, will be in such a dilapidated condition that, if they will not die before long, there surely will not be a pound of surplus this coming season. They had a good fly one afternoon, three or four weeks ago, and were put back into the cellar the same evening. I also had standing out two in Roe's chaff hives. Both are dead. My neighbor is about as badly off; two-thirds of his bees are also gone, and that means no sections or bee-supplies for us this year. The bee-paper is the only thing that will still flourish. Wm. Moershel.

Homestead, Iowa, March 22.

ONE-THIRD MORE HONEY TO WINTER OUTDOORS THAN INDOORS.

I find that it is taking a third more honey to winter bees outdoors than it does in the cellar. Those in the cellar used one pound of honey in 15 days, or very near that, while those in single-walled hives, out of doors, used a pound in 10 days or on that average, for the last 90 days.

Charles White.

Farmers Valley, Neb., Feb. 15.

A PLEA FOR THE BLACK BEE.

Has the black bee no friends, that we see nothing in its favor? For years I purchased Italian queens, and had my apiary well Italianized; but the winters of Northern New York seemed too much for them, and my bees are now all natives; and I believe that, in this location, if a man had an apiary of fifty colonies, and forty were Italians and ten black, at the end of ten years there would not be an Italian left.

Woodville, N. Y., Mar. 9. W. Van Auken.

SMALL APIARIES FOR EXTRACTED OR COMB HONEY.

Would it pay to buy an extractor where one has only 8 or 10 hives of bees? and which stands pay most, those run for comb honey or for extracted? What proportion would you advise to run for comb honey, and what for extracted?

Weldon, Ark., Mar. 3. E. W. Johnson.

[If you have only a few colonies you had better run them all for comb honey.]

ALFALFA, AND WHEN CUT FOR HAY.

On page 115 of Gleanings we read that alfalfa cut for hay is cut before it blooms sufficiently to produce honey. I would not give much for that hay. In this country it produces honey for a while before it is cut, but not as long, of course, when cut for hay as if cut for seed.

Last, Cal., Mar. 27. W. A. H. Gilstrap.

A CHEAP PACKAGE FOR EXTRACTED HONEY.

Candy-pails for honey I find are the best and cheapest thing for extracted honey. When the honey granulates they can be shipped everywhere. My bees are wintering well.

Cokato, Minn., Mar. 21. Fayette Lee.

NOTES OF TRAVEL

FROM A. I. ROOT.

When a railroad goes over the mountains it almost invariably runs up a canyon, and, as a matter of saving expense, the builders take advantage of every depression; therefore when you go over or through mountains on the cars you can not get a view of the world below at all, for you simply see out of the car-window the sides of the canyon; and when you reach the summit and go through a pass, this also is a depression, and seldom gives any view whatever of the valley below. There are some partial exceptions to this rule when the road goes up the *side* of the mountain (like the trail on Wilson's Peak), but not many; and it seems to me, too, that one must go at least part of the way on foot to enjoy thoroughly the mountain scenery. To get health and enjoyment there must be a certain amount of enthusiasm. How shall we get it? I have been thinking a good deal of this lately while writing these papers. Some may say they have not naturally the imaginative disposition that furnishes these "flights." In fact, Mrs. Root has said the same thing a good many times; but she has enjoyed the mountain scenery almost as much as I have. Now, please have faith in your old friend when he tells you *how* to have enthusiasm. Ask God to give it you. Ask him to give you love for and enthusiasm in your daily tasks. Keep praying; and before you know it your prayer will be answered. One element of enthusiasm is a clear conscience — a conscience void of offense toward God or man. I do not see how one can make any real prayer without this. So if you undertake to pray, your inconsistency will rise up before you — that is, if there *be* any inconsistency. Now, don't keep it back if it wants to come. Let the still small voice speak; and when it tells you when you have wronged a neighbor, stop praying right square off. Go and make it right with him; return that borrowed tool, or pay him for the damage you have done it; then, and not before, finish your prayer. Is not this almost exactly what the Savior said? See:

TUNNELING FOR WATER AT EATON CANYON, AT THE FOOT OF MT. WILSON.

> "Therefore if thou bring thy gift to the altar, and there rememberest that thy brother hath aught against thee, leave there thy gift before the altar, and go thy way; first be reconciled to thy brother, and then come and offer thy gift."—
> MATT. 5:23, 24.

Then shall you have enthusiasm; and with the enthusiasm shall come a love for wholesome exercise; and with exercise and a clear conscience shall come health.

I have before mentioned the picnic dinner we had at the foot of Mt. Wilson, after our trip down. You know I mentioned also how I envied people who could drink all the pure water they wanted, at any time and on any occasion. Now, the water that supplies the beautiful city of Pasadena comes from a mountain stream that tumbles down this same Eaton Canyon; and as the waterworks is somewhat extensive and complicated, an old gentleman remains there constantly as superintendent of the works. He seemed glad to see company, and pointed out to us the best drinking-water. I drank considerable—I do not remember just how much; and as it did not produce any disagreeable effect at all, at dinnertime I drank a tremendous quantity of lemonade. Friend Stevenson and Miss McClurkin assured us the lemonade was first class, because they picked the lemons from a tree that grew in their own dooryard. The boys that were along declare that I drank *twelve glasses;* but I think *they* must have been in a hurry to get a dozen: besides, the glass was not a very large one, and probably it "slopped over" a little in filling it up. No matter; I did drink just all I wanted of lemonade and spring water all that afternoon, and rejoiced to feel that I was a well man, especially in this one respect. The enthusiasm and almost constant perspiration probably had much to do with it. You know I have had much to say about doctoring without medicine. Well, here is another weakening and distressing malady cured without *any medicine at all*, unless we call God's pure air, sunshine, spring water, and mountain scenery "medicines."

I was quite curious about the irrigating machinery, and the old engineer seemed quite glad and willing to tell us all about it. A great iron pipe, I should think six inches in diameter, for it looked like a small stovepipe, ran along the sides of the canyon and up the mountain until it reached the spring, 160 feet higher up. This gave an immense pressure, you will notice. Now, this great pressure was utilized in working a sort of injector, using water under pressure instead of steam, of course. Well, this force was made to raise water from another spring or springs lower down in the canyon; that is, this force raised water without any pressure, so as to deliver it into the irrigating canal that supplies the city. The engineer receives a certain salary to remain at his post and look after the waterworks. If I understand it, he was to work at something else or not, just as he chooses. Well, he is a man after my own heart, in that he does not like to be idle; so, just for the fun of it he made a tunnel into the side of the mountain, working at it during his leisure hours. The cut on p. 291 shows some of his work. There was originally a crack or fissure in the rock. With a pick and shovel he made the opening larger, so that one could go in and out without trouble, standing up. I snapped the Kodak on it, and friend Stevenson stood by the side of the opening so as to give one an idea of the size of things. There is a little stream of water that comes out under the plank that runs in at the entrance. After our friend got a little way into the rock he found it so much softer that he could dig it with comparative ease, and with a narrow wheelbarrow he ran out the debris and made a very pretty walk along by the side of the stream of water. He had run his cave in about 100 feet, and he was quite anxious that the whole party should go in to see his work. We were already warm and perspiring from our exercise in climbing; and when we found that this cave grew warmer and warmer, until at the extreme end it was almost like an oven, the party began to protest —especially the women-folks, and we hustled back for the open air faster than we went in. The tin cup at the entrance looked so inviting that we passed it eagerly from one to the other to get a drink of these wonderful waters. Of course, a "tenderfoot" would expect to get *cool* water as it issued from the rocky mountain-side; but the water from this particular tunnel was of about the temperature of common dishwater. Of course, no one said any thing, but passed the cup along for each one to drink. Springs of water are like mines of gold, in California; and our old friend was quite enthusiastic in telling us how to locate springs. He says if you can find a fissure in the rock, or if it is only a crack or crevice, if you follow the fissure into the mountain or hill until you strike the bottom of it you will surely find a stream of water. He says he never knew it to fail.

There is one thing about our trip up Eaton Canyon I thought I wouldn't tell of; but as there is a moral to it, perhaps I had better, after all. Up the rough and stony mountain stream, over perhaps a mile of hard climbing, there is a beautiful fall. After we got there the boys spent quite a little time in fixing the stones so that they could stand near the fall while I took a Kodak view. When all was ready I snapped the machine, telling them that I had got a nice view, and then we trudged back again. When almost back to the carriage I discovered that I had omitted to remove the plug that covers the lens of the Kodak. In a letter just received from friend Stevenson, he adds the following in regard to it:

Friend Root:—Don't forget to give in Gleanings the picture you took of the falls in Eaton Canyon.
Pasadena, Cal., March 25. W. Stevenson.

Not only are the streets and buildings of Los Angeles superior, but the parks that grace many parts of the city, and the beautiful dooryards and gardens, present a spectacle with their semi-tropic vegetation that is almost overpowering to one unused to such a scene. Our first morning in the city was after what might be called a summer shower; and Mrs. Root's enthusiasm at the sight of what constantly met our view in some portions of the city was almost too great for words. Adjoining this we give you one sketch as an illustration. The palms and palmettos will be recognized by all of our readers, from having seen them in greenhouses and at expositions. The tall treelike object in the center of the picture is the dried blossom-stem of the century-plant. These run up twenty or thirty feet in only a few weeks' time. The great quantity of vegetable matter accumulated in the leaves during years of growth seems to expend itself suddenly in the one last effort to produce blossoms and seeds. The plant itself seems to be something on the plan of the modern storage battery, only that it accumulates for years just for the one grand *finale* of a few weeks. I was told several times that the century-plant bears considerable quantities of honey; but I don't think it will be worth while just yet to advertise the seeds for sale as one of our *honey-plants*. The plant dies after this wonderful effort to blossom and make the seed.

Jan. 23d we bade adieu to the beautiful city of Los Angeles. It certainly is at the present time the cleanest and prettiest city I have ever set foot in. The streets are broad and regular, and the buildings are fine. Every night, after traffic has ceased, a number of great carpet-sweepers ("carpet-sweepers" drawn by horses) go over the whole of the paved streets and sweep them almost as clean as the floor of a room. Then immense sprinklers lay the dust, what there is left, so you can cross anywhere without soiling the most delicate shoe. The various shopkeepers, as a rule, sweep the walks in front of their stores so as to have them in keeping; and, altogether, one is tempted to think it some fairy land where "shines undimmed one blissful day." The people are also nice and accommodating, and there is also a very strong Christian element pervading all classes. Some of you may think I am humbugged by glitter and outside show. I am well aware; but, dear friends, I *know* there is at least *much* that is genuine. I presume likely I am of late leaning a good deal toward that little virtue that "thinketh no evil;" but I believe it is through the influence of the Holy Spirit I have been praying for that helps me to see and to find goodness and purity everywhere.

After reading the above to Mrs. Root she says it is all right except the great amount of tobacco-juice spattered on those beautiful clean pavements in Los Angeles very soon after they are so nicely swept. I hope her suggestion may be copied in some of the Los Angeles papers, and

SOMETHING LIKE WHAT MRS. ROOT SAW WHEN SHE FIRST LOOKED ABOUT THROUGH THE SUBURBS OF LOS ANGELES.

that the gentle reproof may suggest the idea of dropping this offensive liquid over the curbstone into the gutter, instead of on the beautiful clean walk.

The city of San Diego is, in many respects, like Los Angeles, but is not building up at the present time. During the three years since I visited it before, it has suffered pretty severely in consequence of being "boomed" to an extent it would not bear. Houses in the suburbs are deserted and empty, and many fine blocks in the heart of the city are unoccupied. A storeroom that used to rent for $150 per year now brings only *$30*. With its beautiful climate and magnificent harbor I can not quite understand why this is so; but I presume it is because so few are really engaged in farming, manufacturing, etc. The Christian element seems active; and when the people get over waiting for a chance for speculation, or for some opportunity of getting money from a fresh "tenderfoot," I predict great things for San Diego.

OURSELVES AND OUR NEIGHBORS.

If any of you lack wisdom, let him ask of God.—JAMES 1:5.

I have been familiar with the above text for many years; but it is not till within a few weeks that I really understood it; or, perhaps I should say, within a few weeks past a new application of it has come to me; and it has helped me so much I want to tell you about it. For many years I have been in the habit of praying for wisdom in a general way. I have admired that little prayer of Solomon's, wherein he asked for *wisdom* rather than riches, long life, and victory over his enemies. I have prayed in that way for wisdom. But some way the subject has seemed too wide for me, and too general. Now for the new application. It is this: When we come to a point where we are undecided what is best to do, especially at times when we feel that we are just a little out of the influences of the Holy Spirit, *then* is the time to make a practical use of the text. Stop right where you are; and, if it be practicable, get away by yourself alone in your closet, and on bended knee ask God for wisdom to decide in regard to this *special matter* that is before you. It may be well enough to pray for wisdom in a general way in your morning devotions, for this, of course, is all right and proper; but the new point is to me, to ask God for just what you want in the line of wisdom at the very time you feel the lack, exactly as you would go for a crowbar to move a weight that you could not move by unaided human strength. And I have often felt that prayer should be one of the tools that a Christian workman uses to get along nicely with his work. Perhaps the first essential to use this prayer in the way I have indicated is to feel your own weakness. A couple of lines in a familiar hymn read:

I am weak but thou art mighty;
Hold me with thy powerful hand.

And that is what we need to feel, and we need to feel it oftener. Especially do those who are in authority need this little prayer in the way I have mentioned—a teacher in the public schools, a public officer, a ticket agent (oh how I do wish we had more ticket agents and conductors who are Christians!), one who has charge of men, a minister of the gospel—yes, most emphatically do ministers of the gospel need to pray for wisdom, not only every hour, but sometimes almost every minute. We pray for the influences of the Holy Spirit in a general way; yet how frequently, when an issue lies right before us, and we are compelled to decide one way or another, we find to our consternation that the Holy Spirit seems to have deserted us. Then Satan whispers, "Circumstances alter cases," or something of that sort, and we decide hastily, and then suffer the pangs of remorse of conscience afterward. In the line of our text, if a matter is to be decided, and it is something involving the comfort and happiness of individuals, by far the better way is to ask a little time to think the matter over. If you are talking with a professing Christian, you need not hesitate to say, "Dear brother, before I decide in regard to this matter I should like to have a little time to consider it, and to pray over it; and I wish you too would think of it and pray over it. If we both do this, the Master whom we both love and try to serve will surely lead us to decisions which shall not be very widely different." Oh what a world this would be if even professing Christians through all their intercourse would do this! I know that some of you will say that many professing Christians would pray over it and decide in a selfish way just as if they hadn't prayed over it at all. Well, now, let us not be too hard on our *neighbors*, but let us come back to our *homes* and *ourselves*. Who has not tried to pray over some quarrel or disagreement, but even while praying has felt that self was crowding so hard to be uppermost, it was almost impossible to give an unbiased opinion? I have myself prayed as I thought quite earnestly, to let the Holy Spirit rule and decide; but as my mind went back to the matter in question, self and selfish interests pushed and crowded so strongly that there was not very much Holy Spirit about it. In fact, when I undertook to write on this text I felt such a sense of my own unworthiness that it seemed almost a shame for one who "practices" so poorly what he "preaches," to undertake to *teach* at all. Nevertheless, I have been helped a great deal in just the way I have tried to tell.

In the first place, we want to recognize that human wisdom is so insignificant compared with God's wisdom that it is hardly worth considering. "As the heavens are higher than the earth, so are my ways higher than your ways, and my thoughts than your thoughts."

Now, the great point is to realize this: That human wisdom unaided is exceedingly faulty. We are biased and prejudiced, even the best of us, by so many circumstances and conditions, that, without this cleansing power of the Holy Spirit, we are totally unfit to decide any thing for the public good. Let us once feel that, and feel the necessity of wisdom from on high, and we are making great progress. Now, this may sound like riddles or enigmas to some of you. Does God really speak now as he did in olden time, and tell us what to do or what to say? Yes, my friends, in one sense he does; but now please don't think that I am going into something visionary or untangible. The religion of the present day is a matter of *plain, simple common sense*, and nothing more; and herein comes in another thing that it took me a great while to learn: How does any one know whether God is speaking, or whether it is an impulse from the evil one himself? Why, by applying a simple rule of common sense and nothing more. The whole wide world recognizes a Christian spirit; and small boys on the streets will tell you pretty clearly what is Christianity and what is not. When the report has gone around that a man has "got religion," even these same small boys on the street have a pretty clear and distinct idea of how the man should *act* after he has got religion. Perhaps some of you remember a story that I have told before. After a revival meeting in our town it was talked on the streets that Mr. —— got religion the night before. One of the small boys declared very vehemently that it was not so; and when questioned as to why he did not believe that Mr. —— had got religion he said, "Because I saw him go down street a few minutes ago, and he had a cigar in his mouth." A crowd of other small boys—street Arabs they might be called stood by; and when they heard his statement, not one of them disputed it. Without discussing the tobacco question here, every small boy seemed to have a clearly defined conviction in his mind that the man who got religion the night before would not go down street smoking a cigar the next morning. Well, now, the same kind of logic or reasoning will tell what the influences of the Holy Spirit would be, or, if you choose, what kind of fruit such influences should bear. One of the first requisites in letting God speak through us, and in letting the Holy Spirit decide matters, is that we avoid haste and precipitation. When you are getting into a bad frame of mind, or when you feel that Satan's promptings are coming pretty thick and fast, you must stop and tell your companion something like this: "I hope you will excuse me, neighbor Jones, but I think we had both better stop right here and take this matter up some other time." If you have the strength of character to do this, you are a pretty safe man. You know what my favorite text says, for I have repeated it often enough: "He that overcometh, and keepeth my works unto the end, to him will I give power over the nations."

Sometimes after waiting an hour you will feel so differently about the matter under discussion that it will astonish you. If, however, you are greatly stirred up by something that has been on your mind a long while, it may take several days to put self down out of the way so that the Holy Spirit can speak to you clearly, telling you what a Christian ought to do. Now look out for a stubborn spirit that is very likely to come in. This stubborn spirit will say something like this: "Can't help it; Christianity or no Christianity, I am not going to be run over in that sort of way by anybody." Look out for all such promptings and counsel as this. It comes from the evil one. I do not mean, mind you, that you are always to submit to be run over; for my experience is, that a consistent Christian is less likely to be run over than almost anybody else. The man who is quiet and cool, and never raises his voice above its ordinary tenor, is the one whom people respect. It is the man who gets to talking loud, and attracting the attention of the passersby with his quarrels and jangles who is most sure to be run over at every turn.

In olden time the prophets prefaced their utterances with a "thus saith the Lord." I do not suppose that the Holy Spirit speaks to us now in just the same way that it did then; but if we think coolly and calmly, with no selfish schemes or feelings in our hearts, but, rather, a feeling of peace and good will toward all mankind, we can be pretty sure to know just what the Holy Spirit would say on almost every occasion. It does not take more than a quarter of a minute to decide what *you* would like to do under the circumstances; but it may take us several hours to fight down selfish impulses so that we can hear clearly and plainly a "thus saith the Lord" in regard to difficult and troublesome matters. Perhaps the greatest obstacle in the way of receiving and acting upon this wisdom that comes from the Holy Spirit is selfishness and self-interest. I have read of some great man who had such a high temper that sometimes he would go off by himself and wrestle with it as he would wrestle with some wild animal. Some of you may smile at such an illustration; but the very man who thinks there is no wild animal inside of him to be whipped and put down is the very man who is dangerous.

Now in conclusion let me urge the importance of my exhortation to-day in a financial point of view. The whole wide world is hunting and clamoring for trusty men—not only men who are honest in dollars and cents, but men who can be relied upon to be cool and steady—always alike—men who will not kick over their whole former record by a bit of foolishness now and then; men who have wisdom to look ahead and see what is coming, and be ready for it. In short, the world wants men of *wisdom*, and it is ready to pay big prices for them when they are found. A collegiate course of study usually gives this sort of wisdom; and men spend long years in the springtime of life that they may acquire this mental drill. And sometimes even *then* they forget the great promise in our little text—"If any of you lack wisdom, let him ask of God, who giveth to all men liberally, and upbraideth not; and it shall be given him."

Let me now repeat once more the principal points of this talk: Ask God for wisdom, just exactly as you would go for a bucket of water to put out a fire. You can not carry a bucket of water with you all the while, neither can you very well provide each morning the water that may be needed during the day. May be you will not need any water at all; perhaps you will need something else; but when you see that water is *needed*, go at once for *water*. When you see that a particular kind of wisdom is needed, go for *that* wisdom, and go straight to the *great Father above* who gave us the promise. Of course, there are emergencies where one can not go off alone. For instance, a neighbor is whipping a horse unmercifully. Unaided human wisdom would be quite likely to say, "Mr. Brown, if you strike that horse another blow I will have you prosecuted." May be you have tried that way of doing. If you have, perhaps you have seen a quarrel between two neighbors, instead of a quarrel between a man and a horse; and I think we should always remember that a man is of many times more value than a horse —not that I mean to excuse cruelty to animals, by any means. In such an emergency as the above, if there is not any time to do any thing more I would breathe the little prayer that I have so often mentioned—"Lord, help." Then I would, if possible, get up near the neighbor who is whipping the horse. There is great gain in coming close to a man. It is like pulling a heavy load. If you want a team to move it, you must have it close up. The very fact of your coming up to him at such a time will usually induce him to slack up a little and think. Besides, by the time you get there you can have time to listen for words of wisdom from on high; and the promptings of the Holy Spirit, or this divine wisdom, will probably be something like this: "Neighbor Brown, I fear you are whipping that horse a little harder than you know. Hadn't you better wait a little until you and he both get a little cooled off?" By the time you have got thus far the prayer you have breathed will have enabled you to have a pleasant, good-natured look on your face, and may be a smile as your neighbor looks at you to see whether *you* are mad and excited too. A little practice in this kind of work helps one wonderfully. And then comes victory. "He that ruleth his own spirit is greater than he that taketh a city." Now, then, dear brother, the next time you feel like saying to yourself, "Oh I wish I knew just *what* to do in this matter!" please remember what your old friend has said. If it is a matter that has been on your mind several days, I would advise you to get up in the morning before anybody else is stirring. Then go off by yourself and pray for wisdom. It need not be a long prayer unless you feel that there are a good many things you wish to tell the dear Savior about it. Don't forget, I beg of you, to pray for all parties that take any part in the matter that troubles you. If there is anybody in the question whom you do not *feel* like praying for, this is the first thing to be got out of the way. "If I regard iniquity in my heart, the Lord will not hear me." And, again, the Savior says, "Love your enemies; do good to them that hate you, and *pray* for them that despitefully use you." So the first part of your prayer will probably be to get *self* down and out of the way. You want first to learn to *love* your enemies, and to pray for them and resolve to do them good. This word "good" used in this sense is to be interpreted by this same Holy Spirit. Instead of getting revenge on an opponent the thought must constantly be before you that you are trying to make him *better*, and, above all things, to lead him to Christ Jesus. Unless you can do this you need not go any further with your praying. No wisdom will be given you, and no victory will come, until you have mastered *selfish* feelings as I have mentioned; but after having done this, oh what a broad grand universe opens before you! It is exactly like climbing the mountains—you have got above earthly storms and passions, and are looking abroad through a heavenly region. Now, remember the promise—"If any man lack wisdom, let him ask of God, who giveth to all men liberally, and upbraideth not; and it *shall* be given him."

HIGH-PRESSURE GARDENING.

BY A. I. ROOT.

THE PRIZETAKER AND SPANISH KING ONIONS.

Friend Root:—In our test of 1890 we had the Spanish King from Henderson and the Prizetaker from Maule. These two onions were so near alike that no one could see any difference, so we pronounced them the same; but in the test of 1891 we had the Spanish King from Johnson & Stokes, Currie Bros., and Leonard, and the Prizetaker from Maule. The Spanish King from Johnson & Stokes and Currie Bros. were nearly alike, but were uneven, and mixed with red onions. The Spanish King from Leonard was a long, pointed onion, and rotted badly before it was pulled, and was not much good. The Prizetaker resembled the first two, but was much larger and more even, with scarcely any mixture of any other onions. But the most noticeable difference was in the tops, the Prizetaker having a different shade of green from any other onion that we had. Now, to answer the question directly, "Are the Prizetaker and Spanish King the same?" I will say that I think they *should* be, but what they are depends on circumstances.

I know of no kind of vegetable seed that vary so greatly from year to year, and from different seedsmen, as do the foreign varieties of onion. Each year sees some new names added, an old one taken off, while the mixture of English and Italian and other foreign names makes the thing confusing. This, I think, is due to the fact that the seed is all (or nearly all) imported, and the seedsman is only a customer, and is not sure what the seed is until he sees it growing, and he has to depend on the reliability of the grower for good stock. I think that, when there gets to be a larger demand for these varieties of onions, the seedsman will have the seed grown under his own supervision, and then it will be more uniform. We also received an onion under the name of Yellow Globe Spanish that was nearly equal to the Prizetaker. The Yellow Rocca also resembled it very much. I think that, in the onions I have mentioned, there is not much more variation, with the one exception, than there is found in the Yellow Danvers from different seedsmen, but perhaps this may be putting it pretty strong; but there is a great deal of difference in the Yellow Danvers when received from different sources.

E. C. Green.

Agricultural Experiment Sta., Columbus.

[Thank you, friend G. It turns out just about as I had expected; and why in the world we shouldn't grow seed here as well as they do in foreign countries, is strange to me. By the way, I have just picked out a lot of Spanish onions from the Cleveland market—great big handsome bulbs, with very small, insignificant necks. These are hard, firm onions, now in the middle of April, and we have planted them out in order that we may raise some seed ourselves. In regard to this matter of seed, you know there has been quite a little complaint lately of celery that would send up seed-stalks instead of making celery. We have recently had the same complaint with carrots. A great many would send up a seed-stalk without making a root of any account. Can the matter be remedied? I will give you just one thing that I know about it. H. A. March had this same trouble; and to see what he could do he wintered over some nice large stalks of celery, and raised seed from them. The result was, that not a stalk ran up to seed in a whole acre. I saw the celery myself. And this is what he did after just once trying. Suppose he had saved the seed from one of these celery plants that sends up a seed-stalk the very first thing—what would the result have been? A great many of our Spanish King onions had great big necks and comparatively small bulbs. As we had no particular use for these we left them in the ground and they all wintered over nicely, and are now commencing to grow. We propose to bunch them up and sell them for green onions just before they start to go to seed. If they should, however, repent of their "evil ways," and start in this year to make a large onion, why, of course we will let them do so.]

THE AMERICAN PEARL ONION.

Although we have had a winter of unusual severity, the American Pearl has once more wintered nicely—that is, sets that were put out in September so as to make a good growth before winter, all came through. Where they were not planted out till October or later, many of them were thrown out of the ground. As an experiment we sowed some seed of the American Pearl some time in July. When we put out the sets as mentioned above, we also put out onion-plants from these seeds. The plants were, perhaps, as large as a leadpencil, with a bulb on the bottom about the size of ordinary sets. These, too, have wintered perfectly; hence I conclude that the American Pearl, either from seed sown in July or from sets planted in September, if they make a growth so as to get well rooted, they will winter over safely in ordinary winters. We tested quite a number of other onion-sets in the same way. Some of them wintered partly—others almost not at all. The Spanish King came out very well. By the way, we have also wintered over cold-frame onion-plants about the size to be planted out. These had no covering except a little straw. Most of them are all right. By the aid of sash they could, without question, be wintered as we winter cold-frame cabbage-plants.

EGYPTIAN, OR WINTER ONION.

You may remember that I mentioned last season that some of our Egyptian sets on our very rich market-garden ground grew to be almost the size of hens' eggs. Of course, we could not sell such sets; and as I didn't know what else to do with them, we planted them in a row about six inches apart. What do you think they did? Why, they straightway split themselves up into little bulbs like potato onions; and now we have a wonderful growth of large green tops and beautiful bunch onions from six to twelve in a bunch. One of these large sets produced 14 fair-sized onions. This Egyptian onion is perhaps the hardiest vegetable we have any thing to do with. It will grow, and look green and bright, at a temperature between 40 and 50. In fact, they have already made a wonderful growth this spring while scarcely any thing else has made a start. The demand for sets has been beyond the supply again; and, by the way, this onion may be divided and planted at *any time* of the year when the ground is not frozen. In fact, you can pull sets from the tops of the onions at almost any stage of growth, and put them in the ground and they will send out roots, and grow. There is something wonderful about this onion-plant and its many divisions and subdivisions. You know I have been talking about writing an onion-book. Well, what I have learned about onions already would make a very fair-sized book; but the more I study it, the more I begin to think that what I *don't* know about onions would make a still bigger book. To one who loves to study God through his works, this subject of getting thoroughly acquainted with and following out the peculiarities and possibilities of even a single *garden vegetable* is, at least to me, exceedingly fascinating. More than that, a rich reward in dollars and cents is pretty sure to pay the one who gets thoroughly acquainted with any line of plants so as to understand what they may be made to do.

PLANT-BEDS WITH SASH, SHUTTERS, AND COTTON CLOTH.

On page 784, Oct. 1, 1891, I described an arrangement of a series of hot-beds with places to put the sash at either end. I want to say that we find it in our work now a perfect success. We have just had quite a little freeze, and every thing in the way of sash was scraped up to cover the plants. After the sash was exhausted we used all the wooden shutters, even dilapidated and broken ones. Then we took cotton cloth for the hardier plants in place of either sash or shutters. The cloth was held fast at the upper or northern side by a pole, and then another pole was put on the south or lower edge to roll it up on, exactly as friend Day does it with his tomato-beds. It has answered nicely; and although we have had some tremendous winds, a heavy rain, and an inch or two of snow, the cloth has answered the purpose perfectly. My opinion is now, that "high-pressure gardening" is to be done largely in these beds. Not only can vegetable-plants be raised at a profit, but last season we raised extra early corn, early potatoes, snap beans, cabbages, and a great variety of other crops not usually put in cold-frames, and we got prices that paid expenses too. Some of you may be inclined to laugh about growing corn in a hot-bed or cold-frame. The corn was planted the last of February, the kernels being put in just ten inches apart. Glass was used over them at first; but when the stalks got so they crowded against the glass they were protected by shutters or cloth. Every stalk gave an ear—sometimes two—even though planted so close, for the ground was very rich, mind you. We started it at 25 cents per dozen ears, thinking that was all our people would pay, but corn grown in the open air a few weeks after that *also* brought 25 cents, because the people had got a little educated to paying that price. Now, I am not sure but they would have given 50 cents a dozen for at least quite a little of it, because it was quite a novelty from the fact that it was started under glass. There is a big field for work here, friends, if you really love the business and enjoy fighting the frost, ice, and piercing winds. The fighting is to be done by these same plant-beds, with glass, shutters, and cloth.

GLEANINGS IN
BEE CULTURE
A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS
Illustrated SEMI-MONTHLY
36 PAGES 7×10
$1.00 PER YEAR

The testimony of the Lord is sure, making wise the simple.—PSALM 19: 7.

SINCE we have had so many testimonies in favor of sealed covers we have had quite a number of letters for upward ventilation and absorbing cushions. In our next issue we will publish a few of them. We hope that none of our friends will imagine that a sealed-cover is so near and dear to our heart that we can not listen to arguments against it.

WE have long needed a United States law for the suppression of adulteration of foods. There is now a pure-food bill before Congress, with a probability of its passing. We understand it has already passed the Senate, and we hope its friends, including Mr. Paddock who introduced it, will be successful in having it become a law. The main feature of the bill is to prevent the sale of adulterated foods in other States than those in which they are mixed. This, we think, will be quite a check upon the nefarious business, and we hope every subscriber will write to his representative, urging the importance of the passage of this good law. Just at this time bee-keepers need it.

DR. MILLER asks, in Stray Straws, how we succeeded in imbedding the wires in foundation by means of electricity, the electricity heating the wire from end to end, so that it will melt into the wax. We were not quite ready yet to report, but perhaps we might say this: We succeeded partially, and are certain that, with the proper battery power, we could imbed and make a nice job. We do not feel so positive, however, that it will pay. Batteries—at least the direct-current or primary type—are expensive, and require to be renewed often. Storage (or secondary) batteries will answer nicely, but they are still more expensive, and require to be stored up with the invisible fluid from some electric-power station. For the average bee-keeper these are not available. It remains for us now to prove whether it *can* be done; and if so, whether it can be done profitably.

IN response to our call for reports as to how bees are wintering throughout the country, about 200 bee-keepers have, up to date, Apr. 12, responded. The reports show that bees, with very few exceptions, have wintered exceptionally well. About a third of the number report no loss, and the remaining two-thirds show from 95 to 98 per cent as the number that have wintered. There are only three or four who report below 60 per cent. The losses, where they have occurred, have been principally in

Iowa, Western Illinois, and Northern Michigan. In answer to the second question, "How does their condition compare with former years?" most of them report "much better."

AT Medina, out of a total of 200 wintered outdoors we have lost only 3, making our per cent stand 98½. One was in a winter case, another in a chaff hive, and another in the house apiary. By the way, the few colonies in the house apiary fared very much worse than those outdoors. During the first week in April brood-rearing outdoors seemed to be progressing finely; but during the last few days a cold spell has set in. What effect this will have in killing off unsealed larvæ we do not know.

THE phonograph is proving to be a grand success in our office. By its aid one typewriter operator is enabled to do the work of nearly two. In fact, one of our girls now transcribes with the talking-machine all the correspondence of E. R. and J. T. C. On the old stenographic dictation plan she had all she could do to handle Mr. C.'s correspondence alone. We suppose the reason why the phonograph is not generally used in offices is because business men who would use them for dictation are not sufficiently expert in handling electrical machinery. The phonograph is, in fact, simpler than a sewing-machine; but it is so new and so different, that, when a thing gets "out of kilter," the average business man, instead of trying to fuss to get it in order, will give it up and go back to the old way. The day must surely come when the phonograph will be used exclusively in all offices where large correspondence is carried on wholly through dictation. It should be stated that the phono-graphophone has not yet proven to be a success; but the Edison phonograph has with us—at least so far.

A NEW POULTRY-BOOK.

IT would seem that the poultry-book business is already overdone; but recently there has come to our table an excellent book entitled "The Chicken Business, and How to Make it Pay;" by H. B. Geer, of Nashville, Tenn., a well-known poultryman, as some of you may know. So far as we have been able to examine it, it gleams with experience. From the preface we quote: "This book is written by a practical poultryman for practical people, and with no attempt at fine style or language;" and such, evidently, it is. To give you an idea of the book we will give you two or three selections:

On page 8, in speaking of yards or runs, he says: "To be a successful poultry-keeper it is very necessary to keep the fowls on the premises divided into small flocks of fifteen or twenty to the flock." In another place he says that fifteen or twenty fowls will usually pay better than fifty or more together. The reason of this, we presume, is on account of disease and many other ills to which poultry are subject when in larger flocks. Again, he says, in speaking of artificial hatchers or brooders, "We would not advise persons of inexperience in poultry culture to invest at the outset in an expensive incubator with the expectation of making a success of it. It is a great deal better and a great deal cheaper to experiment with a 25-cent hen as an incubator at first." The author does not discourage the use of brooders and incubators; but he advises every one to be a little careful how he invests his money in expensive apparatus at the outset. The book is divided into chapters, and every thing is made so plain that any bright boy or girl could, upon reading the instructions, successfully manage poultry, we think. The price is 50 cents. It can be had of the author, or of the publishers, Foster & Webb, Nashville.

THAT CANADIAN IMBROGLIO.

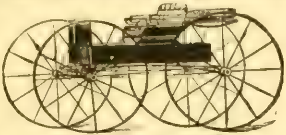
THE unwisdom of incorporating the North American, and the subsequent non-affiliation of the Ontario Society, is still harped on at length in the *Canadian Bee Journal* by two of its correspondents. If the latter had left out, or could leave out, their unchristian and unkind thrusts toward ourselves and two or three others on this side of the line, we might feel disposed to reply in detail. When controversy arrives at this stage we would rather drop out altogether, even if we are placed in an unpleasant light by the other side, although we could answer every one of the allegations. As we said at first, we still insist that "further discussion is ill advised and unwise," especially if it must degenerate into a clannish and partisan spirit. R. McKnight's reply we considered fair and courteous, and so, also, do we consider the criticisms of S. Corneil with reference to our position regarding the best treatment for foul brood.

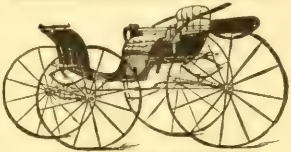
With regard to incorporation of the North American, if, in view of its unpleasant reception on the Canadian side, our American bee-keepers would feel disposed to "throw up the sponge" we would be in favor of doing so, solely on the ground of peace. Perhaps on this point we may differ with Mr. Clarke. Our relations with Canadians in general, up till now, have been of the pleasantest, and we would rather yield a point, or, if you please, "back down"—yes, lose all the advantages of incorporation, rather than not enjoy cordial relations.

THE INTERNAL WATER CURE.

As nothing has been said in regard to this of late, perhaps some of the friends would like to know how it has turned out after longer experience. Well, so far as a forward movement in the line of cleanliness that has heretofore been neglected is concerned I think it has accomplished a great deal of good; but as to curing the great list of diseases that it was claimed to cure by those who sold the secret for several dollars, it is simply a disgrace to those who have peddled it and received money for the information. Some of you will bristle up again, I think quite likely; but, my dear friends, during my travels I made it a point to get the opinions of some of our best physicians. Not only that, I met and talked with many people who used it, and a great many who paid money for the secret. Like almost every other remedy, it is useful in certain cases; but so far as being a benefit when used indiscriminately, it is a mistake. Your family physician can, as a rule, guide you safely in this matter. Several instances came to my notice where its use did harm, without question; and I presume that the *greater part* of those who were so enthusiastic about it a year ago have mostly abandoned it—that is, for constant use year in and year out, as recommended by Wilford Hall and his agents. The idea that our family physicians are hostile toward it because it cuts off their practice is ridiculous; and any well-informed man or woman of the present day should be ashamed of such talk. It is a disgrace to the present state of civilization. Of course, there *are*, here and there, unprincipled physicians; but as a class, the medical men of our age are among the best informed, and, as a rule, they are working hard on this problem that lies before us all—what is the cause of so much human suffering, and how shall we lessen it? Now, when you are tempted again to say that all doctors are rascals, remember it comes next door to saying that "all men are liars."

Now abideth faith, hope, charity, these three; but the greatest of these is charity. A. I. R.





ALLIANCE, GRANGE, LEAGUE

F.M.B.A. Members and thousands of other good men and true, patronized us so liberally last year that we were compelled to buy, build and increase our facilities until now we now have one of the LARGEST CARRIAGE and HARNESS FACTORIES IN THE WORLD. The Alliance Factory runs when others shut down or break up.

"A" Grade $40.

"A" Grade $46.

"A" Grade $72.50.

Send for our handsome, illustrated Catalogue, showing over 100 different styles of Vehicles and Harness, and you will understand why all this phenomenal success and immense business. We actually give more for less money than any Buggy or Harness factory in the world. All goods hand made and warranted for years. Get our prices and compare them with your dealers.

Sections! Yes! Sections!

800,000 all ready for shipment in standard sizes, planed on both sides.

Our customers say we manufacture the finest sections made in Canada.

We are the only manufacturers in Canada of the celebrated A. I. Root Dovetailed hive.

Our one-dollar dovetailed hive includes Leach's improved comb-honey crate complete. By using the above crate the sections are taken off perfectly clean, need no scraping, and are all ready for market. All our hives are furnished with the improved Hoffman frames.

We make a specialty of manufacturing all kinds of bee-keepers' supplies.

Our new catalogue for 1892 mailed free on application. Address

IF YOU WANT BEES

That will just "roll" in the honey, try Moore's strain of Italians, the result of 13 years' careful breeding. T. J. Moffitt, Kemps Mills, N. C., says: "They beat any thing I ever saw in the bee line. They are certainly 'rolling' in the honey now; one of them beats three of my others at work. I would not take $5.00 apiece for the queens. They seem very gentle." Prices: Warranted queens, in June, $1.00 each; 3 for $2.50. Tested queens in May, $2.00 each; select tested, $2.50. Circulars free. 8d

C. M. DIXON, Parrish, Ill.

A B C OF

STRAWBERRY ✣ CULTURE.

A ⁑ BOOK ⁑ FOR ⁑ BEGINNERS.

BY T. B. TERRY.

This is Terry's latest and best work, and has received some very high words of praise. Who that keeps bees does not also have a little garden-patch? If you would learn to raise in it that most luscious of all fruit, the strawberry, with the best results, you can not be without this little book. Even if you don't grow strawberries you will be the better for reading it. Pages one-half size of this. Fully illustrated; 144 pages. Price 35c; by mail, 40c.

A. I. ROOT, MEDINA, O.

Cash for Beeswax!

Will pay 27c per lb. cash, or 30c in trade for any quantity of good, fair, average beeswax, delivered at our R. R. station. The same will be sold to those who wish to purchase, at 32c per lb., or 35c for *best selected wax.*

Unless you put your name *on the box*, and notify us by mail of amount sent, I can not hold myself responsible for mistakes. It will not pay as a general thing to send wax by *express.*

A. I. ROOT, Medina, Ohio

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they wish to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough in these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I have 50 good hybrids and black queens for sale at 25c each, ready for immediate delivery.
6-7d W. H. Heastman, Citra, Marion Co., Florida.

Black queens, 15c; hybrids, 20c; mismated, 25c.
Geo. E. Dawson, Carlisle, Ark.

I have a few hybrid queens, young and very prolific, 35c each; 3 for $1.00. W. C. Gathright,
Toccopola, Miss.

25 mismated and hybrid queens at 40c each. They are large and sprightly, and prolific layers. Stamps taken. J. J. Hardy, Lavonia, Franklin Co., Ga.

KIND WORDS FROM OUR CUSTOMERS.

My goods arrived all right, and I am well pleased. The sections are very nice. SOLOMON LEWIS.
Bellevue, O.

I received the goods in good order nothing lost. I was well pleased with every thing.
Mauston, Wis. C. E. HASKINS.

As to the A B C book, I don't think I ever read a novel that interested me any more than that does.
Diamond, Pa. F. B. ROSS.

I am very much pleased with the goods I received from you. I like the thick slats of the section-holders, and the foundation is the finest I ever had.
Carpenter, Ill. E. SMITH.

I have received your book, the A B C of Bee Culture, and one copy of GLEANINGS, and am very well pleased with them. FRANK ARNOLD.
Deer Plain, Ill.

Goods received Jan. 1, 1892, that I ordered of you Dec. 12, 1891. They came through in good condition, and I am well pleased with them. JAS. A. ADAMS.
Gunn City, Mo.

My order, which is No. 8918, came to hand all right. The extractor is a daisy. The hives are the very thing that I wanted. Your A B C book is very practical. A. J. BLANKENBECKLER.
Greenback, Tenn.

If you make your GLEANINGS as interesting in the future as in the past, please consider me a "sticker." L. G. ENGLISH.
Marysville, O.

[That's plain English.]

Friend Root, you may continue GLEANINGS. I inclose $1.00. I am very much pleased with my sewing-machine. I think it is on the true principle.
Mohawk, N. Y. CHAS. P. BROWN.

How GLEANINGS has improved! If it would only come every week, and as "chuck full" of good sound reading as it now is, it would have no rival. Allow me, Ernest, to congratulate you on your part toward making us a good periodical.
Welton, Iowa. FRANK COVERDALE.

GLEANINGS AS AN ADVERTISING MEDIUM.

I found your journal the best advertising medium last season. I had more orders from the two insertions than I had from other journals in which I advertised 6 months. O. J. E. URBAN.
Thorndale, Texas.

There are other sweets that we get out of the columns of GLEANINGS besides bees and honey—the crumbs that fall from the master's table—those good things our children like to read, and profit by the same. S. F. MILLER.
North Manchester, Ind.

GLEANINGS is always a welcome visitor, or, rather, a welcome member of the family. Your father's notes of travel are worth many times the price of GLEANINGS. M. L. BREWER.
Philo, Ill.

Wife can't give up the "good talks," and I won't give up any part of your journal, although my apiary does not furnish much honey except about one year in five. N. W. FALES.
Innsdale, Cal.

GLEANINGS improves with every issue, but it ought to have more items from Southern bee-keepers to make it of as much use to us as it is to those further north. H. FITZ HART.
Avery, La.

[We are glad to get items of interest from practical men from the South. We desire to make GLEANINGS interesting to all classes.]

Goods ordered of you were received all right. It is almost surprising with what promptness you folks do business. When we order goods from you they are always here before we are looking for them. The sewing-machine gives splendid satisfaction. The lady told me she liked it well, and would just as soon have it as a $40 machine an agent left at her house to try to sell to her before she saw the one I got from you for my daughter. Long life to GLEANINGS and all its helpers. L. DYER.
Morristown, Ind.

I find every thing complete. I am well pleased. The sewing-machine is nicer and better than we expected. I have tried it thoroughly, and find it first-class in every respect. I believe I could secure more sales of machines in this locality by a little work.
Corunna, Ind. SIMPSON FARRINGTON.

We were very glad you were out of the 1890 hives. I like these new Dovetailed hives much the best. Friend Bean says they are the nicest hives he ever saw, and every thing fits so nicely he says he can put these together in one-third less time than the ones he got last year from another firm.
Canaanville, O., Feb. 22. F. J. STIERS.

Job Lot of Wire Netting.

CUT PIECES AT A LOWER PRICE THAN FULL ROLLS.

Having bought from the factory, at our own price, five or six hundred remnants, as listed below, we are able to give you the choice of a great variety of pieces at the price of a full roll or lower. Full rolls of netting are 150 ft. long, and when they are cut we have to charge nearly double the full-roll rate, because it is so much trouble to unroll, measure, and cut, and run the risk of having a lot of remnants on hand. No doubt it is in this way that the following remnants have accumulated. It costs a good deal to get all this in shape so we can easily pick out from the lot the piece you want. But to move it off quickly, we put the price down so you can all have a chance at it. Remember, first come, first served. In ordering, therefore, name a second or third choice, or say that we may send the nearest we can if the piece selected is gone. On 5 pieces deduct 5 per cent, on 10 pieces 10 per cent. These remnants are shipped only from here. If any of you want to secure some, and don't want them shipped till later, when you will order something else, so as to save freight, pick out the pieces you want, send remittance with the order, with request to lay by till called for, and we will mark them as belonging to you. We prefer to ship them right out, however.

LIST OF POULTRY-NETTING REMNANTS.

Width in in's.	Size of Mesh.	No. of Wire.	Cts. p'r Sq. Ft.	Length of each piece. Multiply by the width in feet to get the number of square feet in each piece. Then multiply by the price per foot for the price per piece.

PAINT FOR
BEE-HIVES.

After much experimentation, and a careful study into the paint question, we offer a mixed

**Paint Prepared Especially for Bee-Hives.
It will not Chalk or Flake off.**

We guarantee it to be free from adulterants, such as whiting, barytes, lime, and other substitutes that do not add to the enduring qualities of the paint. Our paint is made of strictly pure lead, strictly pure zinc, and genuine French ocher of about equal proportions, mixed in pure linseed oil. It is generally recognized that there is no pigment more permanent than French ocher; and this, combined with zinc and lead, makes a most durable combination. The resultant tint is a pale straw color. Price: Pint, 35c; quart, 60c; half-gallon, $1.00; gallon, $1.75. Half a gallon will cover ten No. 1 Dovetailed hives two coats.

A. I. ROOT, Medina, O.

NOTE THESE FACTS,
THAT IN THE
PECOS VALLEY,
THE FRUIT BELT OF NEW MEXICO,

Farmers in this valley raise two or three crops a year of grain and vegetables, and five crops a year of hay:

Stock grazes on green alfalfa all winter;

Every farmer in the Pecos Valley is writing to all his friends to come here;

The Pecos Valley is destined to rival any portion of southern California as a fruit-growing country;

It produces nearly every variety of fruit, vegetable and cereal that can be grown anywhere in the United States;

Nearly every species of forest tree can also be grown here under irrigation;

Vegetables and grain can be grown between fruit-trees while the latter are growing to the bearing stage;

We have a home market for all our products at good prices;

We have the most delightful and healthful climate in the world;

The thickest ice formed here this winter was less than one inch thick;

The total snow-fall was less than two inches;

The sun shone on this valley 352 days in 1891;

This climate is a never-failing cure for consumption, bronchitis, asthma, catarrh, rheumatism, etc.;

All pulmonary troubles are relieved by a permanent residence here;

There is just freezing enough here in winter to kill out any and all possible impurities in air or water;

Men can work outdoors with comfort every day in the year;

Our Pecos River water is pleasant to the taste, and healthful;

It is, moreover, a never-failing cure for dyspepsia and liver troubles, and for all diseases of the bladder and kidneys;

It is also excellent water for stock;

All kinds of stock thrive upon it;

Good, pure, cool well water can be had anywhere in the valley by digging 20 to 40 ft.;

And a great many others equally important which we will point out to you when you come here.

Meanwhile send for handsomely illustrated book, map, etc. Address

PECOS IRRIGATION & IMPROVEMENT CO.,

CONVENTION NOTICES.

The first annual meeting of the Connecticut Bee-keepers' Association will be held at Hartford, May 12, commencing at 10:30 A.M. All interested are invited. MRS. W. E. RILEY, Sec.
Waterbury, Ct.

The annual meeting of the Ionia Bee-keepers' Association will be held at the Bailey House parlors, Ionia, Mich., May 11, 1892. John H Larrabee, of the Michigan Agricultural College, will make an address. H. SMITH, Sec., Ionia.

The Southwestern Wisconsin Bee-keepers' Association will hold its next annual meeting in Boscobel, Grant Co., Wis., on the 13th and 14th of January, 1893, commencing at 10 A.M. All members of the association are requested to be present, as the following officers are to be elected: President, vice-president, secretary, assistant secretary, and treasurer. Blank reports will be sent to each member of the association for 1892, with instructions. A cordial invitation is extended to all bee-keepers, and especially to those who would like to join us. Each member will be notified at least one month before said meeting. BENJ. E. RICE, Sec.
Boscobel, Wis.

CIRCULARS RECEIVED.

W. H. Bright, Mazeppa, Minn.
C. D. Duvall, Spencerville, Md.
Otto J. E. Urban, Thorndale, Tex.
J. W. Bittenbender, Knoxville, Iowa.
Leahy Manufacturing Co., Higginsville, Mo.

SPECIAL NOTICES.

CANNED TOMATOES.

We have a large supply of tomatoes of our own canning. They are Ignotums; and as both seeds and juice were separated at the time of canning, the cans contain only the solid Ignotum meat. Price 10 cts. per can, or $9.00 per 100 cans.

SEEDLING TOMATO-PLANTS.

We have quite a surplus in the greenhouse of good strong plants, standing in the seed-bed; but we are having so many frosts that we do not dare risk them outdoors without protection. Under the circumstances we offer them, for immediate orders, for 30 cts. per 100, or $2.00 per 1000. If wanted by mail, add 25 cts. per 100 for postage and packing. We have Livingston's Beauty, Ignotum, and Dwarf Champion at the above prices.

As the trade has hardly yet commenced on cabbage, cauliflower, tomato, and celery plants, we have an unusually good assortment of all of them, including, also, sweet-potato plants. When the frosts let up for good, however, there will probably be a tremendous rush for every thing in this line, and we rather anticipate there will be a scarcity of many kinds of vegetable-plants.

RUBBER STAMPS FOR YOUR NAME AND ADDRESS.

A month ago, in urging you to be sure and sign your name and give your address, we mentioned incidentally that we could furnish you a rubber stamp to print your name and address for 20c, and so we can; but you need with it ink and pads—or, better, a self-inking pad, which costs 25c more. We can, for 25c, furnish you a nickel pen-holder, with sliding pen and pencil in one end, and on the other a rubber stamp, giving your name and address, with pad to ink it, and a tube of ink included, all for 25c. It is usually sold for 50c, and often for 90c or $1.00. If you want this, order our pen and pencil stamp, and be sure to give plainly just what you want it to print. If you don't write very plainly we can not be responsible for errors.

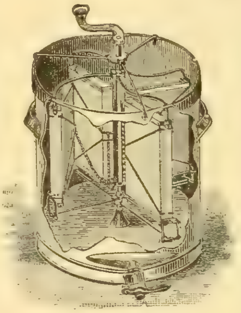
MASON FRUIT-JARS.

Last year, in fruit-canning time there was a scarcity of Mason jars, and the price went up to nearly double what they can be had for now. We advise you to provide yourselves in time before the glass-workers stop for the summer heat. We are prepared to take orders *now* for jars to be shipped direct from Pittsburg, Pa., in original packages, from the first to the fifteenth of June, at the following prices:

Pints (6 doz. in box), $8.00 per gross (12 dozen).
Quarts (8 doz. in box) $8.25 per gross.
2-quart (6 doz. in box) $11.00 per gross.

Remember these prices are good *only for immediate orders*, and to be shipped during the first half of June direct from Pittsburg, Pa. Orders to be sent to us.

STANLEY AUTOMATIC REVERSING HONEY-EXTRACTOR.



As announced in last number of GLEANINGS, we have leased from G. W. Stanley the right to make his automatic extractor, and we bought from E. R. Newcomb his stock of materials and machines unsold. This stock consists of about twenty-five machines, two and four frame. To work it off quick, and give us a chance to put out machines of our own make, we offer these machines as long as they last, at one-fourth off old prices. We will sell the two-frame machines as they are for $9.00; the 4-frame for $15.00. They are crated ready for shipment, with crank direct on the center-shaft. We will attach our new horizontal gear, as shown on page 14 of our catalogue, for $3.00 each extra.

ONE-PIECE SECTIONS.

We are now making one-piece sections at the rate of a million a month. In the five months from Aug. 1st to Jan. 1st we made about one and three-quarter millions; in January and February, one and one-quarter millions; and since the 1st of March we have been turning them out at the rate of a million a month. We have now in stock about one and a half millions of all widths of the 4¼-inch section from 1½ inches up to 2 inches. We have also enough dry lumber in our yard to make about three million more. By the time this is worked up the lumber we have contracted, cut the past winter, will be ready to begin on, and this will make six or eight million more. The quality of the sections is superior to any we ever sent out in former years, and, we believe, equal to any made, and superior to most makes. We contracted to supply one large dealer at a higher price than he was offered other good sections for, because he decided that ours would please his customers enough better to pay the difference in price. We are also making lower prices in large lots to dealers than we have been able to do heretofore. We mention all these things to show you how well prepared we are to serve you. Last year, and the year before, our supply of lumber suitable for sections was insufficient, and, as a consequence, to fill orders at all we were compelled to send out some that were rather inferior for first grade. To many of our friends who received these goods we have allowed a rebate; and to others who mentioned it in their orders we have sent an extra supply of the choice sections we are now turning out. If there are any who have not yet had satisfaction, we want to hear from you so that we may have an opportunity to give you satisfaction, and to give you sections that can not be surpassed by any manufacturer.

HONEY COLUMN.

CITY MARKETS.

NEW YORK. *Honey.* Considerable stock of comb honey on the market, mostly off stock and buckwheat. No demand except for fancy stock. New crop Southern extracted arriving in small quantities, and finds ready sale at from 70@75 a gallon for choice; 65@70 for common. *Beeswax*, quiet, but firm at 27@29, as to quality.

Apr. 23. HILDRETH BROS. & SEGELKEN,
28 & 30 West Broadway, New York.

KANSAS CITY. *Honey.* We report a better demand for comb; but no change in prices. We quote: White comb, No. 1, 13@14; No. 2, 10@12. Amber, No. 1, 10@13; No. 2, 8@10. Extracted, white, 6@7; amber, 5½@6; dark, 5. *Beeswax*, 22@27.

Apr. 20. CLEMONS, MASON & CO.,
Kansas City, Mo.

ST. LOUIS. *Honey.* White-clover honey in comb, 15@16; good white, 13@14. Spanish needle, 12; dark and broken comb, 6@8. Extracted, white-clover, in cans, 7@8, small way; bbls., 5½; Southern strained, in bbls., as to quality, 4½@5¼. *Beeswax*, prime stock, 28½; selected, more.

Apr. 20. W. B. WESTCOTT & CO.,
St. Louis, Mo.

CHICAGO. — *Honey.* — Honey-market unchanged since last reported. The offerings of fine comb are very light, and it brings 15c; dark comb according to present outlook will be about exhausted by May. The price of this is uncertain at 10@13. Extracted sells at 6@7@8. Stock light, and shipments would be sold on arrival. *Beeswax*, 27.

R. A. BURNETT,
Apr. 19. 161 So. Water St., Chicago, Ill.

DETROIT.—*Honey.*—The demand for comb honey is as usual very light at this season of the year. A few fancy lots have sold as high as 14c; but for ordinary lots, 12@13 is what it sells for. Extracted, 7@8. *Beeswax*, in fair demand, 27@28.

Apr. 20. M. H. HUNT,
Bell Branch, Mich.

ALBANY.—*Honey.*—There was quite a brisk demand for comb honey during the week preceding Easter, which enabled us to nearly close out what stock we had on hand. We have much complaint from customers on account of most of the comb honey being candied, which customers object to. Prices range from 6@10. Extracted in moderate demand at 6@8. CHAS. McCULLOCH & CO.,

Apr. 20. Albany, N. Y.

CINCINNATI.—*Honey.*—There is no change in the market. Extracted honey brings 5@8, on arrival. Comb honey is sold at 12@15, for best white, in the jobbing way. *Beeswax.*—Demand is good, at 23@27 for good to choice yellow on arrival.

Apr. 23. CHAS. F. MUTH & SON,
Cincinniti. O.

KANSAS CITY.—*Honey.*—Demand poor, with a large supply of comb. We quote: Comb, 1-lb., fancy, 12@13; dark, 8@9. Extracted, white, 7; dark, 5@6. *Beeswax*, none on the market.

Apr. 20. HAMBLIN & BEARSS,
514 Walnut St., Kansas City, Mo.

NEW YORK. *Honey.* We have no change to make since last quotations, prices hold about the same. Demand is decreasing as the spring advances. Fancy comb honey, 10@12; fair, 8@10; buckwheat, 6@8. Extracted, clover, 6½@7; buckwheat, 5@6; Southern, 65@75 per gallon. *Beeswax*, 27@29.

Apr. 20. CHAS. ISRAEL & BRO.,
110 Hudson St., New York.

SAINT LOUIS.—*Honey.*—Inquiries for strained were frequent, and business more satisfactory. No quotable change in values. *Beeswax*, prime, 28.

Apr. 20. D. G. TUTT GRO. CO.,
St. Louis, Mo.

BOSTON. — *Honey.* — No change in the honey-market. Slow sale and fair stock on hand.

Apr. 21. BLAKE & RIPLEY,
Boston, Mass.

MINNEAPOLIS.—*Honey.*—Fancy white-clover honey in good demand at 16@18. Choice dark selling at 12@14. Strained honey, sale slow. *Beeswax* not wanted; in fact, there is no sale for it here.

Apr. 16. J. A. SHEA & CO.,
14 & 16 Hennepin Ave., Minneapolis, Minn.

PORTLAND. *Honey.* There is no change to note. Fancy extracted white, 1-lb., 18; other grades less; 2-lb., white, 16. Not much demand. *Beeswax*, scarce at 30.

Apr. 12. LEVY SPIEGL & CO.,
Portland, Or.

SAN FRANCISCO. *Honey.* Honey in light supply, and we quote: Extracted, 5½@6½; comb, 10½@12. For the latter, the demand is improving a trifle. Prospects for the coming crop are not very good as far as honey is concerned. *Beeswax*, scarce 25@26.

SCHACHT, LEMCKE & STEINER,
Apr. 23. San Francisco, Cal.

CHICAGO.—*Honey.*—Fancy comb honey selling at 16c; choice, 14@15. Other grades 10@13. Extracted scarce, good demand, 7@7½. *Beeswax*, active sale, 28c. S. T. FISH & CO.,

April 29. Chicago, Ill.

A Four-Color Label for Only 75 Cts. Per Thousand.

Just think of it! we can furnish you a very neat *four-color* label, with your name and address, with the choice of having either "comb" or "extracted" before the word "honey," for only 75 cts. per thousand; 50 cts. per 500, or 30 cts. for 250, postpaid. The size of the label is 2¾x1 inch—just right to go round the neck of a bottle, to put on a section, or to adorn the front of a honey-tumbler. Send for our special label catalogue for samples of this and many other pretty designs in label work.

THE Bee-Keepers' REVIEW

FOR 1892 AND A FINE, TESTED, ITALIAN QUEEN, OF LAST YEAR'S REARING, FOR $1.75. EITHER ALONE, $1.00. FOR $2.00, THE REVIEW, THE QUEEN AND THE 50 CT. BOOK, "ADVANCED BEE CULTURE," WILL BE SENT. W. Z. HUTCHINSON, FLINT. MICH.

P. S.—If not acquainted with the REVIEW, send ten cents for three late but different issues.

SPECIAL MATED

queens reared under the swarming impulse in our Texas apiary, and mated to very yellow drones. Queens and drones from two of the best queens in Texas. All queens warranted purely mated. One queen, Apr., $1.25; 6 for $6.00. May, one queen, $1.10; 6 for $5.50. Our **5-Banded Italians** are the best workers, most gentle and beautiful bees. Safe arrival and entire **Satisfaction Guaranteed**, circular free. **S. F. & I. TREGO, Swedona, Ill.**

In writing to advertisers please mention this paper.

GLEANINGS IN BEE CULTURE

A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS.

ILLUSTRATED SEMI-MONTHLY

PUBLISHED BY A. I. ROOT.

$1.00 PER YEAR MEDINA OHIO

Vol. XX. MAY 1, 1892. No. 9.

STRAY STRAWS

FROM DR. C. C. MILLER.

THAT LEAD-ZINC-OCHER paint mentioned on p. 287 makes a very handsome finish.

FREE DELIVERY of mail would be very handy for bee-keepers in rural districts, in the busy season.

GEO. W. YORK is now assistant editor of the "old reliable" *A. B. J.* A good man for the place, and a nice fellow.

D. L. TRACY, Longmont, Col., says no one in Colorado can raise honey for 1½ cents, the actual cost being about 7 times that.

HUTCHINSON has made a success with his little pictures, and the short sketches add interest. Wish he'd get a picture of Hasty.

STILL THEY COME. The *National Bee Gazette* will make its bow to the bee-keeping public May 7, hailing from St. Louis, Mo. Don't know who is to straddle the tripod.

REVIEW YOUR FIGURES, Mr. Editor, and see if that heading on page 290 shouldn't read "One-half more honey to winter outdoors than indoors," instead of "one-third."

I WAS SURPRISED to find that considerable alfalfa seed is being sold to farmers about Marengo, this spring. I shall be still more surprised if it makes any difference in my honey crop. I'm quite willing to be surprised.

MINNESOTA goes to the head of the class as a hatcher of new bee-journals. Two inside of a year. The last is *The Bee Age*, Spring Valley, Minn., the editor being no less than our friend B. Taylor. Nothing sleepy about him.

"PAST EXPERIENCE," says *B. B. J.*, "tends to prove that the best honey seasons are late ones." Hope that may prove true this year, for up to April 22 we're having mostly March weather in this neck of the woods.

ECHINOPS SPHÆROCEPHALUS is highly recommended by a writer in *Centralblatt*. In this country, I think, it is not considered of value enough as a honey-plant to pay for cultivation. It was largely tried, but who raises it now?

SPRING DWINDLING, the *B. B. J.* thinks, is not so likely to occur in a backward spring. This accords with the view I have expressed, that it is best for those who winter in cellars to keep the bees in till time for dwindling is past.

AMERICAN BEE-KEEPERS, according to R. Riecken in *Centralblatt*, are able to care for 150 colonies per man, often double that number, and harvest an average crop of 45 to 60 pounds comb, and 100 pounds extracted per colony. Hasn't the "Bruder" got that a little steep?

TOOK OUT BEES April 7, when they had a good fly, but maple bloom was either killed or past, and bees could do nothing. Very cold nights, ending up with a snow storm the 14th. Might have been better to have left bees in later.

THAT BEE-ESCAPE of Larrabee's has one one point, I think, in its favor, that he didn't mention on page 282. The large space connecting super with hive, separated only by wire cloth, makes the bees more ready to go down than if the only communication were one little hole.

TILE DRAINAGE, that exceedingly well-written little book by Prof. Chamberlain, is more interesting than many novels, and should be read by every farmer and farmer boy. They'll learn something from it besides drainage. I've just read it through, and I know a good bit more than I did.

ARTIFICIAL HEAT in cellars is objected to by some. Last winter I thought I would try doing without. Found I'd made a fool of myself again. Worst loss for years; 41 per cent died in shop cellar. House cellar is warmer, and the loss was less than 12 per cent. If it had been a severe winter I suppose it would have been still worse.

THE THREE SINGLE EYES of bees have been a puzzle as to their use. Mr. Grimshaw, of England, starts the theory that they are not eyes at all, but bull's-eye lanterns that emit a very feeble light to guide the bee in its work at night. Such production of light is quite common among insects, and the source of the theory gives it some title to respect, for Mr. Grimshaw is an able observer.

"IN WORKING SECTIONS at the side of the brood-nest, the bees cluster on the sections nights and dull days, and that is what stains the cappings," says A. B. Mellen, p. 282. That may be true to some extent, but if your brood-combs are all new built you'll not find the sections much darkened. I'm pretty sure the worst darkening is from bits of the black brood-comb actually used in sealing the sections.

EXTERNAL CAUSES that induce swarming, Larrabee says, "are, an unusual and increasing number of bees in the hive, presence of a honey flow of some degree, drones, etc., one or all. Wild animals seem to breed at stated seasons, because taught so by instinct, but are bees guided by that instinct?" That clears it up in good shape. I understood it "external" to the hive, while he meant "external" to the bees.

AFTER TRIAL I am quite pleased with the plan of wedging up sections in the T super. But I think I like my plan better than yours, Ernest. My wedges are the same length as the followers by ½x¼ inch, and I don't twist them after inserting. Just push one end of the stick down to the bottom at one end of the super, and then lower the other end to the upper surface of the sections. I consider it important to have the stick long.

MUCH IS SAID about the convenience of being able to shift the outside sections to the center of a super and vice versa. I don't think I ever want to shift them thus. It takes time, for one thing, but that's not the greatest objection. A section moved to the outside row is not finished so quickly and nicely as if left in the center. Don't move a section in a super till the mass is finished, then take off the whole thing, and return the unfinished ones in another super.

HONEY VINEGAR.

HOW TO MAKE; BY DADANT & SON.

Friend Root:—Mr. Louis C. Jessing wrote us lately, "Please tell us in GLEANINGS how to make honey vinegar, taking us over the ground step by step, as it were, from the time the honey-water is made, to the time when it will be good strong vinegar; also how long it will take, kind of building used, etc."

There are, in the formation of vinegar, two kinds of fermentation. The first transforms into alcohol the sugar, or saccharine matter of the liquid used; the second changes into acetic acid the alcohol produced. The germs that cause alcoholic fermentation exist around ripe fruits, and, to some extent, in honey, and develop best at a temperature of about 75 to 80 degrees. The second fermentation, which develops acetic acid, finds its germs in the atmosphere, and may take place almost immediately after the other has begun, and long before the saccharine matter has been all transformed into alcohol, so that the mixture may be sweet, alcoholic, and sour, at the same time. It looks rather contradictory to say that a liquid is sweet and sour; but that is often a fact, nevertheless. The more prompt and thorough the alcoholic fermentation, the more readily will the liquid be transformed into vinegar when the acetic fermentation begins.

Honey does not contain the germs of fermentation in sufficient quantity to make a thorough alcoholic fermentation; and when mixed with water and left to itself it will require several months to convert the mixture into an alcoholic beverage, and several months more to change it to vinegar.

If we are not in a hurry, we may succeed in making good vinegar by filling a barrel half full of water, adding 2 lbs. of honey to the gallon of water, and a few gallons of fermented or unfermented cider, keeping it in a warm place, and covering the bunghole with wire cloth or with a piece of thin cloth, which may keep out insects and dust. By this method half a barrel of honey-water may be changed into good vinegar in two to six months, according to the temperature.

As we sell vinegar to our neighbors, but do not care otherwise to keep it for sale, we have been in the habit of keeping two barrels for vinegar. One contains the oldest vinegar, from which we draw for use; the other contains the souring liquid. As we are growers of grapes, and make wine, we are in the habit of fermenting a certain amount of honey-water in our wine-cellar, and this is used only when it has already undergone the alcoholic fermentation, and sometimes with the addition of a little wine, which gives it color, and adds to the good taste of the vinegar. This mixture is kept in the second barrel, both barrels never being more than half full; and as fast as we take vinegar from the first we add to it an equal quantity from the other.

When honey-water has been made in such a way as to make it impossible to weigh the honey—for instance, by washing cappings or honey-utensils, barrels, cans, etc., we test its strength with a fresh egg, which should float, just showing itself at the surface.

The best method to induce a prompt and thorough alcoholic fermentation in honey-water is to mix it with a large quantity, the more the better, of crushed fruit, such as cherries, berries, grapes, apple pumice, or even with the pumice of grapes, commonly called "cheese," just after the fermentation of the grapes. The more fruits are used, the more thorough the fermentation. The mixture should be kept at a high temperature in vats or open barrels covered only with muslin or some light cloth, and the vessels should be filled only about two-thirds, so as to avoid loss, as the mixture rises like bread, during fermentaton. As soon as the turbulent fermentation is over, the liquid should be drawn into barrels. This is usually after a week or so, if the temperature is right. The barrels should not be filled more than half full, as the liquid must be exposed to the air as much as possible, in order to hasten the acetic fermentation which is fed from the atmosphere, as said before. The addition of a gallon or two of strong vinegar will induce a more prompt acetic fermentation. Good authorities also recommend the use of vinegar mother—a slick, slimy substance found in vinegar, and which is said to be decomposed vinegar. This vinegar mother is taken from an old vinegar-barrel, washed clean, cut into pieces, and these are added to barrels of forming vinegar.

After the vinegar has undergone the main acetic fermentation, if it becomes necessary to transport it or to put it into closed barrels, it should be racked, or drawn from its lees. If cloudy, it can be made clear by putting in each barrel the white of an egg, and stirring it with a stick. It will not become entirely clear until the last fermentation is nearly all over.

Honey vinegar is far superior to the best cider vinegar, and can compete successfully with the very best wine vinegar.

There are only two drawbacks to the making of vinegar. It takes a great deal of room, and it spoils all the barrels that are used. The acid eats up the iron hoops wherever it happens to leak, and the wood is often bored full of holes by worms, when not in use.

There is a quicker method of making vinegar on a large scale, but this requires a special building and apparatus. We will give it to your readers, however, if desired. In making vinegar as above described, any ordinary shed, such as is used for a cider-press, will do, if used during warm weather; and to keep the vinegar, any ordinary cellar is suitable; but, as we said before, a temperature of about 80 degrees will best aid the making of vinegar.

Hamilton, Ill., Apr. 1. DADANT & SON.

EUGENE SECOR

AS A BEE-KEEPER, BUSINESS MAN, OFFICE-HOLDER, AND POET.

The convention of the North American Association to meet in the city of Washington, in the year 1892, is to be presided over by the Hon. Eugene Secor, of Forest City, Iowa. The ancestors of the Secor family, refugees from the religious persecutions of the Hugenots, came from France in 1681, settling in New Rochelle, N. Y. In 1841 Eugene was born in Putnam Co., N. Y., and it was his good fortune to be kept there on a farm until he attained his majority. In 1862 he went to Iowa, entering Cornell College at Mt. Vernon. A brother, who was county treasurer and recorder, as well as postmaster, enlisted to hold up his country's flag, and Eugene abandoned his college course to take charge of his brother's business, thus occupying two years. Had his health been more robust, he probably would have borne his brother company in the army.

Asked what his business is, aside from bee-keeping, Mr. Secor replies, "When the bees are not swarming, and no public duty calls me, I 'recreate' by running a real-estate and abstract office in the daytime, and writing for the papers at night." Let me schedule the public offices which he has filled for the past 25 years, and it will not be hard to see that hardly more time could be allowed for the real-estate and abstract business than to make it a "recreation."

In 1868 he was elected clerk of the District Court, Winnebago, Ia., and was twice re-elected, serving six years, having been deputy a year previous. In 1875, elected county auditor; re-elected in 1877, making four years' service. In 1878, elected mayor of Forest City, where he still lives; and at the expiration of four terms as mayor he was elected a member of the city council, which position he still holds.

At the age of eighteen he became a member of the M. E. Church, where his services have been in demand. He has officiated as leader of the choir, is one of the church trustees, is also steward, and was elected by the "conference" of the church one of the board of trustees of Cornell college, to which position he has been re-elected to serve a second term of three years. He is a member of the executive committee of that board. He has reached the highest position to which a layman can attain in the M. E. Church, being elected a lay delegate to the General Conference. Nor are his religious works strictly confined to his own church, for he is president of the County Bible Society.

He has borne his share of the burden of educational matters in his own city, by acting as a member of the school board and being president thereof.

In spite of his special interest in apiculture he has a leading hand in agricultural matters, having organized the agricultural society of his county (Winnebago), of which society he was president for two years, and in 1888 he was elected by the State legislature one of the board of trustees of the State Agricultural College, to serve a term of six years. He is chairman of the executive and finance committee in said board.

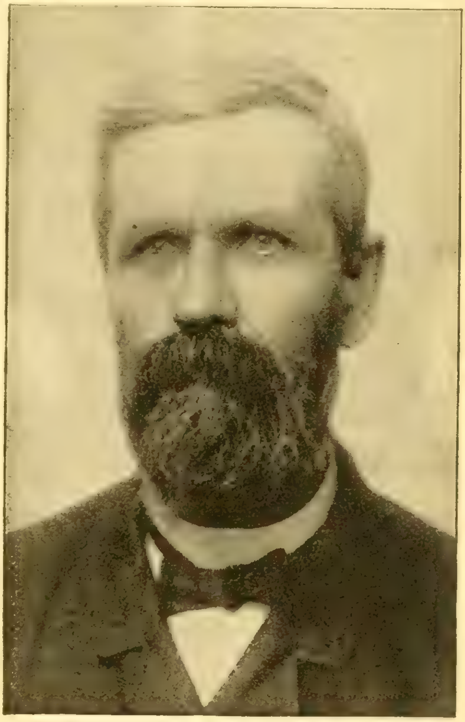
The State Horticultural Society has shown its appreciation of his services by re-electing him as president of that society and giving him charge of one of its experiment stations. The State Bee-keepers' Society elected him president in 1891 and 1892.

However busy he may be at other things, he will have to find time in June to go to Minneapolis as one of the two delegates from the 10th District to the National Republican Convention, to help nominate a candidate for president of the United States.

Bee-keepers are more or less familiar with his business-like style in apicultural writing, and he has been a somewhat irregular contributor of prose and poetry to the *Iowa Homestead*, *Housekeeper*, *U. S. Dairyman*, to all the bee-journals, to horticultural papers, local papers, etc. He was apicultural editor of the *Iowa Homestead*, and now he holds the same position on the *Farmer and Breeder*.

As a writer of verse, it is to be regretted that he sometimes shows a reckless disregard for the laws of grammar and versification; but the true spirit of poetry is in him, and bee-keepers may well be proud of him as their poet-laureate. Indeed, wipe out of existence the bee-keepers' songs written by Eugene Secor, and there is little left worth their singing. The great trouble is, that he writes only as the spirit moves him, and the "moving" seldom comes. A year or so ago he sent me a single stanza of a bee-keepers' song (urged to the writing, I think, by Dr. Mason), asking me if I thought it would do. Of course it would do, and I advised its completion. That's the last I ever heard of it. It may never get further than the first stanza, and it may be completed. If it is, it will be a good song.

Most of the readers of these pages are more or less familiar with the poetic writings of Mr. Secor, and he has been especially happy in his dialect songs. Take that one in which the good-natured German has been hearing the big stories of what bees will do with little or no care. He gets a colony of bees, and then sings, care-free,—



EUGENE SECOR.

Oh, I ish von of dose happy bee mans,
I don't got to vork any more;
I loafs all day on der apple-tree shade,
Or shmokes mine pipe on der door.

More or less of this vein of humor seems ready to bubble up at all times in his writings. Even the tortures of la grippe have for him a funny side, and he writes,—

I don't feel well. I can not sleep.
The chills along my backbone creep.
I'm tired and nervous. I go home
And call the doctor, who, when come,
Says, "Grippe."

Then after describing how himself and all the neighbors are affected in all parts of their internal economy by microbes or bacteria, he thus earnestly apostrophizes:

Ye microscopic sinners, go
Where ye belong—that is, below.
Haunt us no more forever, please,
Thou Russian, Frenchified disease,
La Grippe.

After all, I like best the poems which show his tender side. I think the right kind of a heart never grows old, and Eugene Secor's heart seems to be of that sort. The poem, "A Love Letter," finely shows this tender side, with a quaint touch of the humorous. No proper idea can be had from any short quotation; but after a description of his anxiety to meet again his loved one, that involuntarily pictures to your mind the ardent young lover, he ends up:

For love is in the *present* tense, no *future* doubts can chill;
Besides, the one who longs for me, 'twixt anxious hopes and fears,
Has been my wife and true love, lo! *these five and twenty years.*

While you smile at the neat little trick that has been played upon you, on discovering that it is a grandfather, and not a youth, who is talking, the whole effect is such that tears are very near the surface.

If room permitted, "My Sweetheart" (his sweetheart was the baby), "Papa, Come Home," and others, might be mentioned. But I can not forbear the mention of just one more, "Father, Hold my Hand." After picturing a little one tucked in for the night, with her many odd questionings, finally ending with the request, "Papa, will you please hold my hand?" the poem ends:

When I lay me down for that last long sleep,
And bid all my loved ones good-night,
Shall I my sweet faith in the Father still keep,
And trust him to bring me to light?

Shall I rest my hand in my dear Savior's own,
And all my vain questionings cease?
Or shall I go out in the silence alone,
When death doth my spirit release?

But to the last question I am sure the poet would make answer:

Ah, no! I shall *not* go in silence alone.

Spare in form, somewhat above medium height, iron-gray hair and beard, Mr. Secor's whole appearance impresses you as belonging to a man of force; but in another respect the face belies the man, for it gives the impression of inflexible sternness, with no hint of the genial, kindly nature that lies back of it. Modest and quiet in demeanor, you might be with him for some time without finding out what he was.

Mr. and Mrs. Secor seem proud of their two daughters and two sons; but the latter, although men grown, have been so sadly neglected in the matter of accomplishments that neither of them smokes cigarettes nor belongs to a base-ball team.

A bee-keeper of twenty years' experience, Mr. Secor's many other duties forbid his going beyond the number of about 75 colonies, and these he has mostly in eight-frame Langstroth hives.

Marengo, Ill. C. C. Miller.

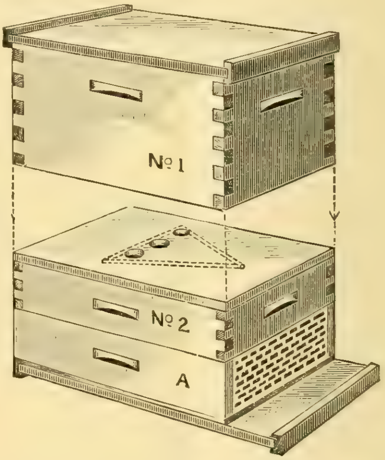
AUTOMATIC SWARMERS, AGAIN.

PRATT'S VERY LATEST.

Bro. Root:—I send you by this mail a model of another application of the swarmer. The sketch above will illustrate how it is applied to any loose-bottom hive. No. 1 is the hive containing the colony expected to swarm. No. 2 is an empty super or honey-case set on a rim of any width, which is shown at A. This rim has one of its ends removed, and a piece of excluding zinc covers the opening and forms a very wide, light entrance.

The super and rim rest on the bottom-board exactly as a hive-body would; and the board having the triangle bee-escape is placed (zinc down) on the super—just as you would apply a bee-escape board to any hive. The apex to the escape should point to the front of the hive toward the entrance. Over all is at last placed the colony expected to swarm. When they do swarm, the queen will be trapped in the lower apartment, and the returning swarm will join her there, after missing their queen.

This arrangement does away with the extra hive and stand, and is nearly as cheap. The only drawback to it is, that it can not be applied to a tight-bottom hive; but perhaps the men using these hives would be willing to cut two or three auger-holes in the bottom-board of them for the sake of checking swarming, or they could shift the combs up into the upper story and use the old hive to catch the swarm in. A zinc honey-board, first placed on the bottom-board, and the super to catch the swarm placed over this, will answer the same purpose as the rim with one end covered with zinc as shown at A, but there would not be depth enough to hang in frames for the bees to work on.



PRATT'S LATEST AUTOMATIC SWARMER.

If one has a surplus of hive-bodies they can be used to catch the swarm in, and the zinc honey-boards will work in well for them.

My patent lies in trapping the queen in a new hive and causing the swarm to join her by the entrance they have become used to working through many days before the swarm issues.

Beverly, Mass. E. L. Pratt.

[We believe that the swarmer above illustrated is considerable of an improvement over the one formerly presented to our readers by Mr. Pratt, good as it was. The feature of the latest one is, that both hives are supported by the same bottom-board, and this makes it unnecessary to level up an extra bottom-board in direct line with the other. The plan seems to be specially adapted to the Dovetailed hive. It is well known, that two of its supers make an equivalent to one body, and that the same can be used for holding the ordinary brood-frames. All we need, then, is a perforated escape-board situated between Nos. 1 and 2 as above, and an extra super with one end open, covered with perforated zinc. While we have not tested either one of Mr. Pratt's devices, from a theoretical point we believe they possess features not found in any other.]

ARE THE BEES OF ITALY YELLOW-BANDED ?

IN WHAT PART OF ITALY THE YELLOW BEES ARE FOUND IN THEIR PURITY.

Following a statement of a correspondent, that he had been from one end of Italy to the other and failed to find any yellow-banded bees, you seem to have questioned his veracity, with a result that a controversy has sprung up. Now, as a matter of fact there are very few yellow-banded bees in the country known as "Italy;" and, what is more, there is no mountain or other barrier to keep them from mixing with black bees; consequently they "shade off" to blacks.

If you have a copy of Frank Benton's "Bees" [if you have not a copy you will find a reprint in the *British Bee Journal*, on page 81, for March 1, 1885] you will see that in it he says: "A few years ago there was quite a discussion in the American bee-publications as to whether black bees existed in Italy or not, and very likely many are not yet clearly informed in regard to this point. An examination, however, of back volumes of the leading Italian bee-journal, *L'Apicoltore* (Milan), would set this point at rest in the minds of all, for plenty of Italian writers on bee culture have stated that very dark bees, not possessing the three yellow bands, exist in various parts of the peninsula and on the adjoining islands. In that portion of the central plain having as its northern limit Bergamo, its eastern limit Nerana and Mantua, the Apennines on the south, and on the west Milan, we find Italians in their purity; also below the Apennines between Genoa and Rome. Outside these regions they shade off into hybrids."

Native black bees also exist in Liguria; so you will see, by reference to a map of Italy, that you can travel from the extreme length of that country without meeting with native yellow-banded bees; therefore it will be seen that the word "Italian" is clearly not the name they ought to have been known by, and is sufficient to explain why I prefer to call the new race I am getting from Tunis "Punics," instead of Tunisians.

The Romans learned agriculture from the Pœnians, and it is highly probable that they introduced the bees cultivated by the Pœnians, because the black bees of Italy more closely resemble the Punics than the German race; but where did the yellow-banded race come from? I am satisfied they did not originate on Italian soil. Probably the Romans, struck with a difference in color, imported some yellow bees; and these, being put in one district, and multiplied, have maintained their yellow blood because it preponderated in quantity; therefore all yellow-banded Italians are imbued with black blood, probably Punic, or, at least, a dash of it, which has caused them to be liked.

One reason why I think this is so is because preference is always given to dark or leather-colored bees, for gentleness and working qualities—these dark bees, of necessity, having most black blood in them; hence, if this dark blood is so valuable it is nothing but logic to go to the fountainhead and get it in its purity in the shape of Punics, and let the yellow bands slide by; for no known pure yellow race has turned out quite satisfactorily. Where the Italian yellow bands came from I know not—probably the original race, which is most likely—has had some other race of bees fused with them, and may be now known as Cyprians or Syrians.

I think the bee-world ought to find a nice short name for yellow-banded bees from Italy. The best of them came from Switzerland. Why not give them the English name, "Ligurians"? It was used here before they reached America. It may not be correct; but it can be understood to mean only yellow-banded Italian bees.

CAN PUNIC QUEENS BE SOLD AS CHEAPLY AS ITALIANS ?

Judging by the letters at hand from readers of GLEANINGS who have addressed their letters, as per my *nom de plume*, many want to try the Punics, but they say the price is too high in America, and seem to think they can get them cheaper here. Of course, I am pleased to hear from any one who wants to give Punics a trial; but I don't want them to run away with the idea that queens can be reared in England as cheaply as they can in America. In the first place, the climate is against us for the work. But in rearing Punics there is another difficulty to contend with, to get pure mating—and all ask for price of tested queens—viz., that, if any strange drones are on the wing within six miles it is almost impossible to get pure mating, no matter how many drones one may have flying. I cautioned friend Pratt about this at first, and he subsequently found it out, that, no matter how easy it might be to mate Italians and Carniolans true, it was no easy matter with Punics until drones were generally killed off, and then mating to preserved drones.

There are three plans I am following, besides requeening all my neighbors' stocks all around with pure Punics; viz., to raise queens early, before other drones get on the wing; do it late, after drones are killed off, and between these to resort to the Mohler system; in fact, the latter will be used the whole season through, so that my untested queens will have a fair chance to be all purely mated; but all this means trouble and expense, which, of course, has to be paid for.

I am also arranging for the exclusive use of an island in the Atlantic, and expect to obtain good results in the way of sending *hand-picked* drones, to mate with selected queens; thus if I can't secure individual mating I shall at least get it to one out of a selected number. What I am aiming at is to supply queen-breeders with true breeding queens, and not to supply every one with a cheap queen; i. e., try to undersell American breeders who have every thing in their favor. A HALLAMSHIRE BEE-KEEPER.

Sheffield, England.

[We find, by looking at the map, that our Italians, and, in fact, about all the Italians that have been imported into this country, have come from the region described by Mr. Benton as having nothing but pure Italians. It is of but little importance to us whether there are any black or hybrid bees in certain parts of the peninsula or not; but it is a fact, nevertheless, that all the Italians we have received since we have been in business have been nearly uniform in color, markings, and general characteristics. It is very possible, as you hint, that the Punics may be closely related to the dark Italians. We have Punic queens in our apiary now, and we shall take pleasure in watching them very narrowly this summer. We doubt, however, whether we shall be able, or, rather, whether it would be advisable to attempt to raise dark bees in our locality, since it is so thoroughly Italianized—that is, permeated with yellow blood. As the Punics look so much like black bees—that is, to the average bee-keeper—it will be very difficult to tell when we have pure stock, on account of the general prevalence of the German bees throughout the United States.]

RAMBLE NO. 58.

IN THE SAGE BRUSH.

The Hotel Temescal is the center around which South Riverside revolves. The South Riverside Land and Water Company have developed a water supply from canyon and from artesian wells, and propose to make a city equal to famous Riverside, fifteen miles to the north. South Riverside has a population of about 800, is rapidly growing, and so are the hundreds of acres of young orange and lemon trees; and in time the town will amount to something.

I inquired of mine host whether he knew where Mr. Edward Bonfoey lived; and in the morning he conducted me to the west end of the hotel veranda, and, pointing across the mesa to the Santa Ana Mountains, said he, "Mr. Bonfoey lives in that white house on that plateau away up on the side of the mountain."

"Well," said I, "Mr. B. roosts in an elevated position. I should say that I have a two-mile walk to get there."

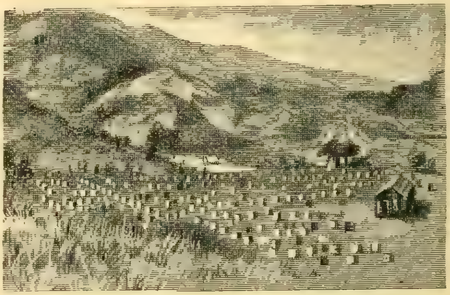
"Yes; and when you walk it you will find it over four miles. The atmosphere is so clear in this country that objects many miles away appear not half the distance they really are. A mountain twenty miles away appears really to be only ten."

I soon started for Mr. B.'s by rapidly putting one foot before the other across the mesa.

Another beauty of this new country is its fenceless condition. There are no little stifled two-acre lots hegded in by stone walls, rail fences, and hedge-rows of elders and briers; but the pedestrian can strike across the country in a bee-line for the object to be attained, and find but few obstructions to his onward march. After an invigorating walk of about an hour the foot of the mountain was attained. A sharp climb of about half a mile up a graded zigzag road put me on the plateau and at the residence of my friends with whom I had become acquainted at the convention in Los Angeles. I was greeted by two not very ferocious dogs and Mr. and Mrs. Bonfoey. The residence of our friends is like thousands of such houses in California where the family has started a home and is improving the wild surroundings to make it some time in the future a place of beauty and value. The house is a simple one-story cottage, with front and rear room with canvas partition, and a lean-to for a kitchen. The visitor needs a little caution about leaning back against the walls. An inadvertent leaning against the canvas would result in the catastrophe of suddenly going into the next room unannounced. The houses here are not built for warmth, but merely for a place to gather to at meal time and at night, and the Rambler has seen scores of houses in the embryo form of a tent, and others with a light frame covered with cotton cloth.

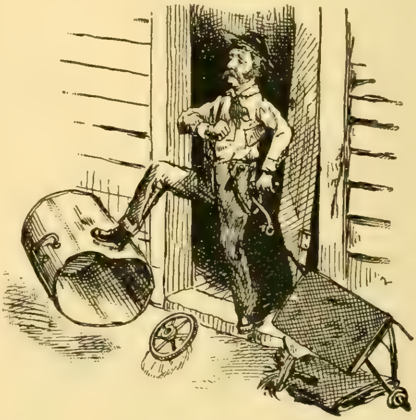
We soon visited the apiary, and were met several rods away by several skirmishers. They followed us in, and, with their reinforcements, obliged us to resort to veils and smoke. Mr. Bonfoey and wife have a joint apiary of about 260 colonies.

There is a little spice of romance in the establishment of this apiary. Mr. B., a young man, had a small apiary, so also had a young lady schoolteacher some bees. They put them together and ran them for a season. But it happened after a while that the young man, every time he tasted honey, would think how sweet that schoolteacher looked with that gypsy hat on; and the teacher, every time a bee passed by her, imagined it to be a Cupid. Such a condition of things naturally led to the calling-in of the parson, *and now that apiary is just booming.* The apiary is very nicely located on a little plateau down the mountain from the residence. It has the usual California honey-house, a building about 10x12, a honey-tank, and a large sun extractor. Mr. and Mrs. B. manage their apiary for comb honey, and put upon the market a gilt-edged article. Their yield during the past season was light; but the bees were in good shape for another year. At the time of our visit, about Nov. 1, they were flying very lively, but getting no honey. October and November are the dryest months of the year; the long dry season is near its end, and rains are soon expected, to replenish the earth again.



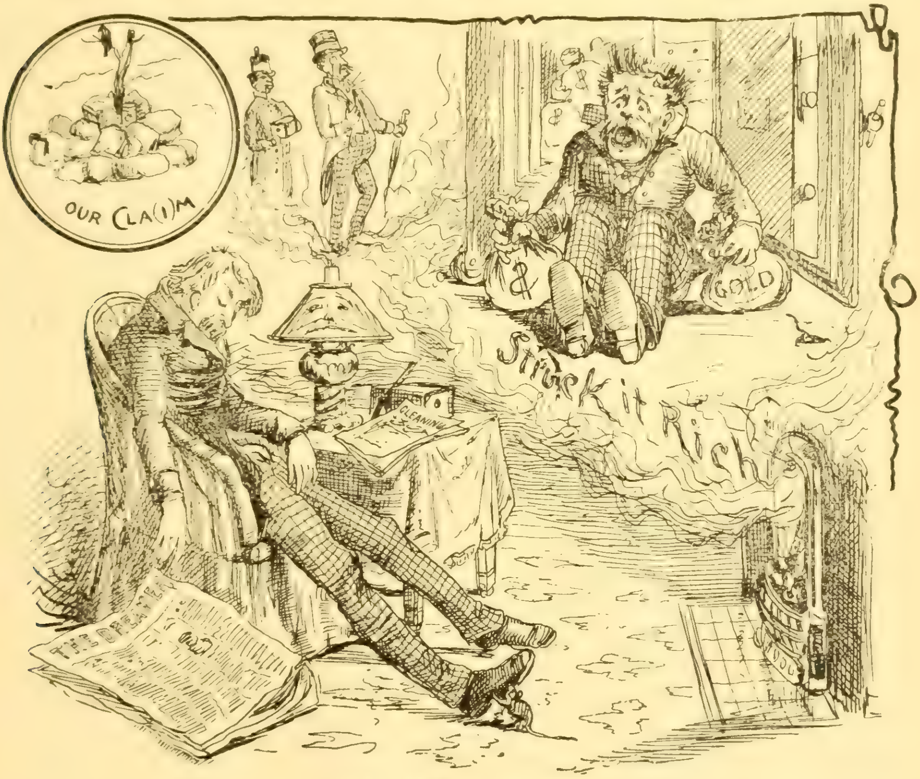
THE BONFOEYS' APIARY IN CALIFORNIA.

This apiary is in the genuine sage district; and to my inexperienced eyes the pasturage seemed to be unlimited. The flowers that yield honey here are, first, in March, alfilaree, mountain mahogany, lilac, and manzanita; in April and May, balled sage and white sage; and, a little later, sumac and wild buckwheat. It would be impossible to adequately describe the acreage of these plants. The apiary is at the entrance to the Hagadorn canyon. Let us ramble for a mile into its winding way and behold nature's handiwork. The entrance is quite broad; and out of it, and extending far across the mesa, is the dry bed of a creek (dry now, but a torrent in the rainy season), and called the *wash;* and wherever you find it there is an



"WHEN THE EXTRACTOR DIDN'T 'GIVE DOWN' IT WAS KICKED ALL OVER THE APIARY."

abundance of honey-producing plants peculiar to it The semblance of a road follows the wash, now in it or on the right or the left. The sides of the mountain soon draw closer, and rise in many places so steep and rocky that even vegetation recoils from the dizzy heights. The further we penetrate, the more obstructions we meet in the form of stones and a scrubby growth of bushes, and we have to scramble and wriggle our way along. At length we reach an old deserted lime-kiln, and halt. We might pursue our course up the canyon for several miles, or until the summit of the range is reached. These upper ranges are unoccupied bee-pasturage, and will be for a long time, as a road can not be maintained in the canyon without great expense, on account of the annual wash-outs it receives. Opposite the lime-kiln, in the perpendicular face of the rocky mountain-side, was a genuine California bee-cave with a small entrance, and of unknown depth. The bees were streaming out and in as though there were immense numbers within their safe abode.



THE RAMBLER DREAMS.

About every two hundred yards the main canyon was entered by side canyons of greater or less depth and length. The whole mountain was thus cut up into ranges and peaks, and the multiplied surfaces covered with sage and other honey-producing plants. There is no timber on these mountains except a few scraggy live-oaks, and thus the honey-plants have free range. The water company's pipes for obtaining water are laid far into the canyon, and I was surprised to find one of them nothing but common stovepipe. In our eastern climate such a pipe for conveying water would soon rust out. The pipe itself would last a long time here, but it was also preserved by the lime and other ingredients held in solution in the water, which in a short time completely line the pipe with a rocklike substance.

When we emerged from the Hagadorn we entered another smaller canyon and found the apiary of Mr. De Pee. The owner lives in a very romantic place in the mountains, and is surrounded by all of the comforts of life. The apiary I must, however, say was in a dilapidated condition. The hives were unpainted and full of cracks, and were leaning at various angles, their entrances showing unmistakable signs that skunks were doing their share toward running things. The honey-house was a rough shed with the door awry, and roof-boards off. The general wreck and ruin of the place was probably owing to the fact that the apiary was in charge of a helper who runs things on the rare-and-tear principle. When the extractor didn't give down properly, it was kicked all over the apiary. The hives were probably not kicked around much, but the little oak-trees looked as though they had been subjected to a hard time. Still, this apiary produces honey, and any quantity of absconding swarms.

Having seen all of the bees in the vicinity, we next turned our attention to locating a mining claim. Various kinds of minerals crop out of these mountains; and Mr. Bonfoey, seeing unmistakable signs of something having the possibility of millions in it, proceeded to lay claim to it. He first stated in writing his claim in full, adding his signature, to which also was appended the Rambler's name as witness. This document was then inclosed in a tight tin can. We then built a monument in the center of the claim, the claim extending 750 feet north and south, and 300 feet east and west from the monument. We first stuck up a scraggly pole, then piled a large number of stones around it, placing the tin can and the document near the top. This gave fair warning to everybody that we had laid claim to all that was valuable on that piece of land, all the way down to China. The Rambler has a share in the mine for lifting some of those big stones, and expects at no distant day to strike it rich.

Thus in airy castle-halls of gold and precious stones dreams the RAMBLER.

SPRAYING FRUIT-TREES WHILE IN BLOOM.

SOMETHING THAT SETTLES THE MATTER.

Mr. Editor:—I read with great interest the discussion on this question, which occurred at Albany, and was very glad of the outcome of that discussion. I am sure that bee-keepers owe nothing but the kindliest feelings to Prof. J. A. Lintner. He is one of our most able, most candid, and most cautious entomologists. He had previously believed that it was unwise to spray fruit-trees while in blossom, and had advised that no one do so. At Washington, it seems, several entomologists expressed the opinion that there was no danger to bees in such early spraying. I regret that official duties as secretary of Section F prevented my being present at the discussion of the entomological club, where these sentiments were expressed, or I should surely have corrected them, and should have shown that they were erroneous, as I could easily have done from careful experiments which we have made here at this college. Prof. Lintner, supposing the points made to be well grounded, changed his opinion and resolved in future to advise spraying at any desirable time, without reference to blossoms or bees. But before acting, he came before the bee-keepers and expressed his convictions and the reasons for them. Upon hearing the opinions of bee-keepers, and learning of their experience, he at once changed his decision, and will continue as before to advise all to spray with London purple or Paris green only after the blossoms have all fallen from the trees. Surely there was a fairness and candor about all of this which rightly claims our respect and admiration. From a long acquaintance with Prof. Lintner, it is just what I should have expected.

I regret that I could not write you earlier regarding our experiments in this matter, which I am sure settle the question beyond doubt; but you know how four months' absence from home fairly swamps a man with work. This, together with larger classes than usual, have given me no time till now to consider the matter and write you the facts.

Mr. Elwood's article shows that he, one of our best-informed apiarists, as well as Dr. Lintner, feels that the matter is in an unsettled state, and pleads for more experiments that we may know the exact truth in relation to this important matter.

I am very happy to give you in advance the experiments which we have made, that I am sure will convince all. These are now in type, and will soon appear in the Report of the Michigan State Board of Agriculture, so there is no need that any other station should demonstrate these facts, except that, the more that do such work, the sooner will the results be known to the people, and the sooner will practical results be obtained.

Let me premise by saying that, in several cases in Michigan and other States, especially Illinois—States where the value and safety of spraying were first demonstrated, and hence where spraying has been most general—there have been serious losses of bees at the time of apple-bloom. Not only did the mature bees die off rapidly, but there was extensive mortality of the brood. These colonies were strong, and had survived the period of the so-called "spring dwindling." Every well-informed experienced bee-keeper like Mr. Elwood knows that such mortality at such time was previously unknown. In every case, large orchards in the immediate vicinity had been sprayed with the arsenites while the trees were in bloom. Previous to this I had tried several experiments in feeding bees sweetened water, with the common London purple and Paris green of the drugstores added in the same proportions that we use it for spraying. In every case the bees were poisoned. Yet they did not die at once; indeed, they lived many times longer than would be necessary to carry the poisonous liquid to the hives and store it there. This explains why the brood is also poisoned. As these people wrote to me of their losses—quite a number have done so, and from at least three States—I had no doubt that the spraying at the wrong season was the cause. 1. The poison would do it, as I had repeatedly proved; 2. The poison was thrown on to trees while in bloom, and the flowers had been freely visited by the bees; 3. Such loss of bees in this manner and at this season was entirely unprecedented in our bee-keeping history. I at once recognized the danger, informed the bee-keepers directly interested, proclaimed through the bee-papers the dangers that threatened bee-keepers, warned fruit-growers of the danger, and urged them for their own interests, as well as for the good of their bee-keeping neighbors, *never to spray while the trees are in bloom.* I have also tried to secure legislation that would prevent such untimely spraying.

No bee-keeper need be told that negative testimony counts for little in this matter. That some one has sprayed his trees while in bloom, and yet no bees were known to be lost, would deceive an entomologist who was not an apiarist; but a bee-keeper would know that the spring is often so cold that the flowers secrete almost no nectar, and the bees are often unable to fly at all. While, then, in many cases, spraying the trees while in bloom would cause no loss, yet in another case when the weather was mild so that nectar was abundant, and the bees out in force, the loss would be most serious. I presume this explains the reports from the entomologists at the meeting in Washington.

Our experiments the last summer, already in print (Report of Michigan State Board of Agriculture. 1891, p. 127), are as follows:

HOW STRONG SHALL WE USE LONDON PURPLE?

Some years ago we tried a series of experiments to determine the minimum strength of London purple or Paris green that would surely prove effective in the destruction of insects. The conclusion was, that 1 lb. to 200 gallons of water was as weak as we could safely use it. This year we repeated the experiments. We used two species of oak-caterpillar—*Anisota stigma*, and *Anisota senatoria;* a hairy caterpillar on the oak—*Halesidota tesselata;* the cabbage caterpillar—*Pieris rapæ;* the potato beetle—*Doryphora tenlineata*, both larva and imago, and the honey-bee. All except the honey-bee were treated outdoors, on the plants or trees, and all, including bees, were fed in cages in the laboratory. We used the London purple, 1 lb. to 200, to 300, to 400, and to 500 gallons of water. In every case 1 lb. to 200 gallons of water was quickly fatal. The weaker mixtures were not satisfactory, especially on the older larvæ and the imago. The weakest mixture, 1 lb. to 500 gallons of water, failed to do thorough work in every case. The other mixtures, 1 lb. to 300 gallons of water, and 1 lb. to 400 gallons of water, were tardy in their action, and did not do the execution that 1 lb. to 200 gallons did.

One lb. to 200 gallons of water killed the honey-bees and the imago potato-beetles almost invariably within twenty-four hours. We find that larvæ succumb to the poison more quickly than do imago, and that young or small larvæ die more quickly than do older ones. Thus our experiments agree with those previously made in fixing upon 1 lb. to 200 gallons of water as the most desirable proportion to use in all cases. There is so little difference between London purple and Paris green that the same strength should be used with both poisons.

POISONING BEES.

We see from the above that the standard mixture—1 lb. of either London purple or Paris green to 200 gallons of water—is fatal to the honey-bee. This makes it imperative that fruit-trees be not sprayed while in blossom. It may be done just before or at any time afterward, *but never during the time of bloom*.

The above, written last October for our Report for 1891, settles the matter positively. When we add, that during bloom is not the time to spray; that for bud-moths and fungi it should be done earlier, and for the codling moth later—not till the blossoms have fallen from all the apple-trees—we thus see there is no possible excuse for spraying while the trees are in bloom; while there are very important reasons, as we have just seen, why no one should spray while the blossoms are still on the tree.

It has seemed to me, and I am now stronger in the faith than ever, that every State should pass a law making it a serious misdemeanor to spray our fruit-trees while in blossom. I do not think such a law would need to be used much, if ever; but as an educator it would do signal service. It would act as our foul-brood and yellows laws have. When men find that there is a law against any proposed course of action, they will almost always hesitate before they act. In a case like this, where there is no cause for wrong action, but every reason for doing that which will work no one ill, but the most good to all, then surely if a legislative act will have influence it should be urged by all, whether directly interested or not. Is it not wise for every bee keeper to agitate this matter, that the public may be educated at least, and that such legislation may be secured as will aid to prevent any spraying during the time that the fruit-trees are in blossom?

Agricultural College, Mich. A. J. COOK.

SPACE UNDER FRAMES FOR WINTERING.

FIRST SWARMS, ARRANGEMENT OF HIVES, ETC.

W. Z. Hutchinson says there is one point that ought not to be neglected in preparing bees for winter—that of leaving a space below the combs. I am sure he is right. We have been practicing the above for several years now, and know that it has been a great benefit to our bees. Before raising them, many colonies would become clogged up at the entrance, both in the cellar and out of doors, long before spring. If in the cellar it would be impossible to clean them out. We could clean the entrance for a little way back in the hive, but they would soon become clogged up again. Such colonies that were thus clogged up seldom came out in the spring in good condition, and many of them would die in spite of being carefully nursed.

Mr. Hutchinson recommends a rim two inches high. We use but one inch to 1½ inches, and find that sufficient; but we raise the hive two inches or more at the back, which enables the bees to drag out the dead bees and keep the bottom-boards clean. Bees are tidy little housekeepers. It seems to worry them to be in a situation where they can not keep their hives clean; and for this reason I would not let the rim extend clear round the hive unless there were an entrance under the front of it, as the bees that fall in a hive should be in a position where they can be easily dragged out. If they remain in the hive and mold, it causes the bees to become diseased; and if it is unhealthy for bees, what must it be to human beings living above them? Yes, we think he speaks truly when he says this space is a wonderful aid in bringing the bees through the winter in fine condition.

Our bees do not now seem to be dying off so much as in the first part of the winter. They seem more quiet at the same temperature, and we do not see any difference as yet in the loss of bees from those wintering on honey-dew and those on sugar syrup.

"I saw it stated in a paper a short time since that the first swarms were the ones that furnish the honey. The parent colony rarely lays up more than enough to supply them with food." Now, in our experience if a swarm is put into an empty hive with all their combs to build, the swarm would not get as much surplus as the parent colony would; so it depends altogether on how we treat the swarm, whether it gathers more or less than the parent colony. Were I purchasing bees I think I should as soon take the parent colony as the swarm.

In the picture where Mr. Root is represented as sitting on a hive with several hives around him near enough to work without rising and walking from one to the other, is a good suggestion. In order to do much work we need to study economy of steps, which saves time, just as a thrifty housewife does. The person who runs back and forth from pantry to kitchen, and from cellar to garret, with no thought how she may save her steps, accomplishes but little work compared with one who economizes her steps as well as her time. But as to the slates or tablets on top of the hives, I am sure I should jostle them around so much I should lose all they were meant to indicate. Probably Mr. Root means us to sit still.

I have such an abhorrence of any thing "wapperjawed," or mixed up together, I must say that the straight rows look the prettiest, and I believe I should prefer them for looks' sake if it did take more time to manipulate them, and were not quite so handy. Sometimes I have need to pull two hives together, but they are always an "eyesore" to me until I get them squared and trued up again.

Brother A. I. says we know he has always been interested in wells and springs; but we have wondered, when reading, what he was *not* interested in. He gave us a very interesting account of our brother's, Samuel Axtell's, home in South Dakota, next station west of Mitchell, more than we had ever learned of the country in all brother's letters; but they do sometimes have terrible blizzards. About five or six years ago three of brother's boys, young men, started to their own farm, three miles away, one morning; and by the time they had gone half a mile a blinding blizzard caught them, and they could proceed no further, neither could they go home. As they were near a deserted house they unhitched their horses and went in. For three days they were unable to leave that house. One of them, who had a wife and children, risked his life and went back home; but the other two preferred to remain rather than run the risk of being lost in the storm, although they had nothing to eat, and no feed for their horses, and had to keep on the move much of the time to keep from freezing.

A sure sign of swarming, says the *Canadian Bee Journal*, is the backward and forward movement of the bees upon the alighting-board.

I have often noticed the same shaking movement; but instead of a backward and forward movement it was from one side to the other, holding on to each other by their fore feet, wiggling their bodies from side to side with all their might. I used to think they would swarm the same day, or soon, but they did not always. I noticed their wiggling in that way this summer in our home apiary, where we had but one swarm, and none from that hive. I should like to know what makes them wiggle so. They act like a lot of little children who are wonderfully pleased over something.

Dr. Miller's big brush is all right, provided he can get the grass and weeds (which we can generally get, all we need, and more); but in one of our out-apiaries this summer we could get but very little of either grass or weeds. The ground was so bare that we retained the old brush and gathered what we could and wrapped around it, making it fresh on the outside.

In the *Fancier's and Breeder's Journal* it is mentioned that Mr. Root says, in convention, I think it was the Northwestern, that it is unprofitable for bee-keepers to breed for any pure race, as many of his customers asked for hybrids and would have nothing else. If hybrids are really as good for honey-producers as the pure race, then why change more for the pure? Our experience is, that, in a real good year for honey, a good hybrid will gather as much as a pure colony; but in a poor year the pure colonies are ahead, and are much easier handled—that is, the Italians. MRS. L. C. AXTELL.

Roseville, Ill.

[There is no question but that the space under the frames, especially for cellar wintering, is a good thing. We arrive at the same result by leaving off the bottom-boards and piling the hives on top of each other in such a way that the one above stands over the space between the two others below, *a la* Boardman.

The reporter in the *Breeder's and Fancier's Journal* must have got things pretty badly mixed when he quoted us as saying that it was unprofitable for bee-keepers to breed for any pure race. We have never knowingly given utterance to such a statement. We might have said that bee-keepers as a class do not make any very great effort to keep their Italians strictly pure.]

ALFALFA, OR LUCERNE.

THE STATEMENT THAT IT IS CUT BEFORE IT BLOOMS IS ALL FOLDEROL.

I have noticed with considerable interest that the quality of lucerne honey is coming to the front, as we in this section consider it equal to the best honey produced anywhere. Now, what I wish to say is, that we have a continuous honey-flow from it, commencing about June 1st and lasting from three to four months. We do not know what it is to have a poor season for honey. Of course, some seasons are better than others; but we always get a surplus. All this talk about cutting lucerne before it blooms is all folderol, so far as this section of country is concerned. A farmer who would cut his hay before it bloomed would be looked upon in about the same light as one who would cut his grain before it was headed; and there is so much difference in time of cutting after haying has commenced that some are cutting their first while others are cutting their second crop. In fact, we are haying all the time for three or four months. And, besides, there are thousands of bushels of seed raised which is cut only once, generally the latter part of September or the 1st of October, and then our roads and ditches are completely lined with some which is never cut at all. We also have sweet clover, but the bees do not work on it any more than on the lucerne.

RUNAWAY SWARMS OCCUPYING HIVES WHERE BEES HAVE DIED FROM FOUL BROOD, AND PROSPERING.

Did you ever hear of bees going into an old hive where the bees had died with foul brood? About a year ago I was called upon by my neighbor, Mrs. Streeter, to look at her bees. She had two swarms which were all dead, as I found on examination, having apparently died with foul brood. I was surprised, a few days ago, when her son came and asked me to come and look at the bees again. I asked him if his mother had bought some more bees, as I supposed she had cleaned up the old hives as I advised her.

"Oh, no!" said he. "The bees have all come back. They stayed away only about three or four months."

I went and found bees in both hives, one having a good strong swarm, while the other had only a few robbers. I did not think it possible for them to thrive in such a hive of combs as those. E. M. WHITING.

Mapleton, Utah, Mar. 14.

INCREASE BY PURCHASE VS. DIVIDING.

HOW TO SECURE INCREASE BY SPREADING THE BROOD.

On page 893 of last year's GLEANINGS Mr. A. C. Brown, of Smithfield, Tex., asks if it would be cheaper to buy bees at $4.00 per colony or divide, using full frames of foundation, and feeding sugar syrup to have it drawn out. And on page 131 of this year's GLEANINGS is an article from L. Stachelhausen, "How he does it;" but he fails to give the information asked for.

I will endeavor to give Mr. Brown what light I can on the subject. 1. As soon as it will do, or as soon as the nights are warm enough not to chill the brood, go through your 45 colonies and spread the brood, placing one or two empty combs in the center of the brood-nest. In seven or eight days go over them again, doing the same thing, keeping the unsealed brood as near the center as possible, this time drawing one or more frames of brood from the stronger colonies, and give them to poor ones. Repeat this once a week until all are strong, and at the same time feed, if necessary to keep up brood-rearing. Now you are ready for increase. Your queen-cells should be ready, about eight or nine days old. Now for the divisions. Take from each colony the queen with half the brood, honey, and old bees. Place them in a hive on a new stand, closing the entrance with wire cloth for 24 hours. Now open up, and the most of them will remain. Now look through the others; destroy all queen-cells, and introduce your queen-cells, which should hatch in two or three days. In one or two days look through to see if all are right. If any cells are torn down, replace them. Now fill your hives with full sheets of foundation. Never use starters if you can avoid it, as they will be filled out with drone combs.

When they are ready for the upper story, fill it with frames of foundation; raise one or more frames of comb from below as baits; crowd the frames rather close at first, spreading them as they are drawn out, placing outside ones in the center, and you will have nice straight combs drawn in due time. I think you will find that they will cost you a great deal less than four dollars per colony, besides the experience and fun you have. I can't side with our Texas friend. I have no short cuts, but find that I get well paid for all fussing that I can do. I should like to read more from our Texas brethren, as our State is so different from others.

Linn Grove, Texas. Z. S. WEAVER.

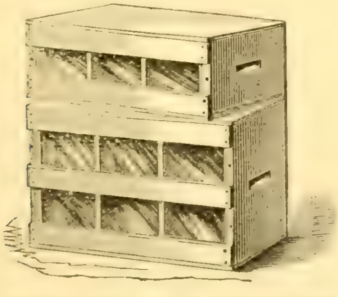
[The instructions given above are good in the main; but for the benefit of beginners, perhaps some limitations ought to be made. There is much danger in spreading brood. Many times we have cold nights and days, even after we *think* the weather is settled for warm. The result is, the brood is killed and the colony is set back. As a general thing it is best for beginners to let nature take its own course. Mr. Weaver's plan for dividing the bees may work, but we prefer to do it this way: Put the queen, one-third of the brood, and two-thirds of the bees on the new stand. A large part of the bees, not used to the new stand, will return to the old one. The consequence will be, that each stand will have about an equal division of bees. The new stand will have one-third the brood; but it has the queen, and therefore the power to go right on with brood-rearing, while the old stand with two-thirds of the brood will have to wait until they can raise a queen; therefore they ought to have the more brood.

We tried this plan of dividing last season, and it worked very nicely. As a general thing we secured about an equal division of the bees, and both colonies would increase to about the same strength, both having equal advantage in the first place as near as we could make it.]

SHIPPING-CASES.

THE ADVANTAGE OF A DOUBLE-TIER CASE OVER A SINGLE-TIER.

One way of making our honey look well, so as to find a ready market, is to have a nice shipping-case—one that will show off the honey to the best advantage, and insure its safe shipment, even if it costs a trifle more. I know that, at the present price of honey, the cents have to be counted pretty closely. But the question is, whether we lose or gain in the long run. The shipping-case was brought up for discussion in the Chicago convention, and I believe the majority present were in favor of the single-tier case.



12-LB. SINGLE-TIER AND 24-LB. DOUBLE-TIER CASES.

We have always used the double-tier case holding 24 sections, and perhaps for that reason I am prejudiced in its favor. I know it costs a little more, and hence many condemn it. Perhaps we ourselves may some day. But I don't believe there is any other case that will show off the honey to as good advantage as the double-tier 24-section case. There is less wood and more honey shown by it than by any other case I know of. Many say it does not ship well, and I presume they are right about it as they use it and as we formerly used it. We piled one tier of sections on top of the other, letting the upper tier of sections rest on the lower ones; and I must say, using it in that way is very objectionable; for, do the best you can, you are likely to have a sticky, dauby mess of it, as there will be broken sections unless every section is exactly square; and even if it is, there will still be the weight of the upper sections resting on the lower ones, which is sometimes a severe strain with the bumping and jolting they must undergo in the cars. But as we use it we do away with all these objectionable features, and the only objection I can see to it is its cost. It does cost more. But, doesn't it pay? We have always thought so.

Our cases are made for 24 sections 4¼x4¼x1 15/16, using 12 sections in a tier. Between the two tiers we use a board 13¼x7⅞x¼. Each tier is separated into three compartments of four sections each by two little boards measuring 4⅜ *long* by 7⅞x¼. It will be seen that these little boards project ⅛ inch higher than the sections, so that the board between the upper and lower tiers can not rest upon any of the sections. Practically it is the same as six separate cases of four sections each, with all the advantages of a double-tier case.

I think no one will deny that these cases do look nice. They are a nice size to handle easily, but their main superiority is that they show so little wood and so much glass and honey. For that reason they look better than any other case I know of.

To begin with, it is not possible to use as wide glass in the single tier as in the double. Now look at the cut. You will see that, in place of the one central cleat in the double-tier case, there must be four pieces of wood in the pile of two single tiers, 12 lb., the cleat and the bottom of the upper case and the cleat and top of the lower case. If cleats 1¼ inches wide are used, and 1¼-inch stuff for tops and bottoms, then you have 1¼ inches of wood in the one case against 3 inches in the other—less than half as much. As we now use sections 1⅞ wide, the dimensions of our cases will have to be changed. EMMA WILSON.

Marengo, Ill.

RETAILING-CASES FOR COMB HONEY.

HOW TO IMPROVE THE APPEARANCE OF THOSE RETURNED.

Those who ship their honey away to be sold on commission in some distant market, and never expect to get the empty cases back again, will find nothing to interest them in this article. There may be some, though, who, like myself, sell a great deal of honey direct to grocers, and expect to get the cases back and use them over and over again. These may like to read something on how to keep them neat and presentable. Very likely you are getting many of them back from the grocers about this time, so I will speak of it now, though it may seem a little out of season.

Some grocers will keep a case so neat and clean that it can be used several times before it begins to look dingy and dirty. Others will return a case so daubed and smeared and stained that it seems as though every thing that could stick to it was represented there by sample. After this has been scrubbed off, it still looks so dingy that your thoughts turn to paint.

I used to paint all my retailing-cases with regular oil paint. A dark color shows off the honey best, and shows dirt the least, so I settled on a very dark blue as the best color for the purpose. When I came to repaint them, which is often needed, to keep them looking well, I found that ordinary paint dried too slowly in winter to suit me. The cases would seem perfectly dry; but somewhere, in the handholes on the lower edges, there would be a little paint that would rub off, and a little of that intense blue paint went a long way. So I adopted asphaltum varnish. This is very cheap —cheaper than paint—and a couple of coats of it produce a rich glossy black that contrasts well with white honey.

One of its chief merits is that it dries so quickly that any thing painted with it may be handled in an hour. Its fault is, that it is easily marred; but a coat of it thinned with gasoline is readily applied whenever necessary, and dries very quickly. Sometimes a little rubbing with furniture polish is sufficient to make it look new again. Carriage black is more durable than asphaltum, but is more expensive.

If you want to letter or ornament your cases, it may easily be done with a stub pen and thin brown japan. For larger letters a wide shading-pen may be used. Unless you are an expert you will probably find a pen better than a brush. Just before the letters are dry, brush over them a little gold or bronze powder.

Blue and gold or black and gold make a very pretty combination. Probably a painter could improve on my methods. If he will tell us how to do so, I shall be glad. A very important point in selling honey is to have it look nice, and a neat case helps greatly in this.

The large retailing cases will do very well in some stores, but most groceries rather prefer a smaller one-story case that may be easily moved around, carried out of doors, or set on the counter or shelves as they prefer. For their convenience the cover should drop into rabbets instead of being simply laid on top, so that it may be easily kept in place. J. A. GREEN.

Dayton, Ill., April 5.

DOUBLING OUR COLONIES, ETC.

PLAIN DIRECTIONS FROM DOOLITTLE ON HOW TO INCREASE NATURALLY AND ARTIFICIALLY, AND HOW TO SECURE A CROP OF HONEY.

A correspondent writes, "I have three colonies of bees in Root's L. hives, and wish to increase them to six this coming season, and secure all the honey in sections possible. How shall I proceed?" If the correspondent is so situated that he can allow natural swarming, I would say, put the sections on as soon as the hives are full of bees, and when little bits of new comb are being built here and there about the hive, this showing that new honey is coming in from the fields. Now, if the hive is full of bees, and no little bits of comb are being built, I should withhold the sections till I see these bits of comb; for if put on sooner, the bees will be quite liable to gnaw or eat holes in the foundation given in the sections; for bees seem to have a mania for doing something when they are populous by way of tearing things to pieces, on the principle that "Satan finds some mischief still for idle hands to do." On the other hand, if I see bits of comb being built before the hive was full of bees, I would withhold the sections till there were plenty of bees in the hive; for if the sections are put on before this, much of the heat required for brood-rearing will go into the sections, thus keeping the colony from increasing in strength as fast as it otherwise would. When swarms issue, set the hive to contain the new swarm on the stand occupied by the old colony, moving that to a new location, when the bees are to be hived into the new hive, and the sections transferred from the old hive to the new. In this way the new colony will immediately enter the sections and go right on completing them the same as if nothing had happened. In eight days after the swarm issued, open the old hive, when, as a rule, the young queen will be found hatched; and if so, cut off all the other queen-cells which may remain, thus knowing that all after-swarming is done away with. If the cells are cut out on the sixth day, as many recommend, you are not sure that after-swarming will be prevented, for the bees have larvæ that are still young enough to be converted into queens, which is often done when we have many after-swarms, only they are a little later in coming than what they otherwise would be. After cutting the queen-cells, put the sections on the old colony also, only I would not put on over half of the full capacity for section honey, as this old colony will not be liable to make as much section honey as it would if it had not been moved from its old stand; but both old and new will make more collectively by this mode of procedure than by any other with which I am acquainted. If I could not allow of natural swarming, then I would proceed as above till swarming time arrived, and the colonies were making preparations to swarm, when I would take three combs of the youngest brood in the hive, bees and all, being sure the queen was on one of these combs, and set them in a new hive, setting this hive on the old stand and moving the old to a new stand. I would fill out this new hive with empty combs if I had them; if not, with comb foundation, and transfer the sections from the old hive into the new. By leaving five combs of the oldest brood in the old hive, and all the bees which adhere to them and the hive, there will still be bees enough adhere to it to fully protect the brood so none of it will chill, as frequently happens by other modes of division, where too many bees return to the old stand. If no queen-cells are started in the old hive at the time of moving it, wait twelve days about cutting out the queen-cells, when we are to proceed as in the other case. In cutting off queen-cells it is well to shake the bees off the combs, otherwise some cells may be missed, in which case swarming will as surely result as it would had all been left on. The above is the way I work an apiary where I wish to double my colonies, and I like the plan much. If the hives used are ten-frame instead of eight-frame, then I would use four with the newly made colony, and leave six in the old hive.

"WHO WILL PROVE ME WRONG?"

On page 202 I find these words from the pen of E. France: "Young children, and all young living things, are apt to get out as early as they can, and exercise themselves; and would a young bee be contented to stay in the house during its youth and do housework? I can not believe it. I believe they go out as soon as they are able to do so. They want to go out and see the world—it's natural. On the other hand, the old bees, like other old folks, would be more inclined to stay at home and do the housework. I simply throw these thoughts out as a suggestion. Who will prove me wrong?"

I am very glad friend France throws this out only as a suggestion; for had he said positively that it was so he might have misled many. Young or old bees may be made to do almost any work not usually done by such bees, by throwing the colony out of its normal condition, as friend France did by taking the comb away from that swarm as fast as built; but, while what bees may do under such circumstances is interesting, yet what bees *do while in a normal condition* is what interests us the most. That young bees do this "housework" when the colony is in a normal condition is very easily proven, regardless of what Bro. F. believes. Give a black colony of bees an Italian queen about the tenth of June, and the first Italian bee will have hatched in that colony about July 1st. Now watch the entrance of that hive and see when the first yellow bees are seen at the entrance on the wing, and, unless all of my watchings have been in vain, none will be seen before the afternoon of July 6th or 7th; but put only hatching brood in a hive, and young bees will be seen on the wing on the third day, thus showing that, when a colony of bees is in a normal condition, young bees do not go out "as soon as they are able." Next, look through the glass part of the hive, and you will see these young yellow chaps poking their heads in and out of the cells, showing that they are doing housework by way of feeding the brood. Now watch this hive every forenoon for nine days more; and, if I have made no mistake, no yellow bees will be seen going and coming with loads, but all black bees. Next, look in the sections where comb is being built and honey stored, and the most of the bees there at work are Italians, "doing housework"— building combs, don't you see? If this is not sufficient proof for Bro. F. that he is "wrong," let him make this one of his experiments also.

Borodino, N. Y., Apr. 20. G. M. DOOLITTLE.

UPWARD VENTILATION.

AND IN FAVOR OF ABSORBING CUSHIONS.

I should like to add my testimony in favor of upward ventilation. We have followed the practice many years, and have been so generally successful in wintering our bees that we consider it a very necessary feature. We winter out of doors, the hives packed in chaff. The propolis-covered sheets are replaced by woolen; and the rough cap which takes the place of the summer one is filled with chaff (not too full) held in place by cloth tacked over it. A piece some six inches square is cut out of the center of the cap cover, and over this is tacked wire cloth to keep out mice. This certainly gives every advantage for the escape of moisture. Perhaps I should mention that, over the whole, there hangs an A roof to protect from rain and snow. It is necessary to remove the woolen sheets in the spring as soon as the bees become active, or they will themselves begin the work of removing them.

"There is a great deal in location," said a bee-keeper who made us a call a few weeks since. "Now I know why you are so successful in wintering your bees," said another a dozen years ago as he stood in our apiary and threw out his arms to the encircling forest. But location, it seems to me, is not every thing. At the close of the season some years ago our apiary consisted of 61 colonies, and every colony in the spring was in fine condition. A bee-keeper a mile distant had 60 colonies in the fall, but had not a single one in the spring. I do not know all the reasons for failure in this case, but I am sure that, if our bees had, like his, been left unprotected till extremely cold weather, and the hives were full of frost, and then subjected to the disturbance of packing in chaff, I should have needed but that reason for failure.

I suppose the old "Wiley lie" is responsible for a part of this serious statement which may be found in the February *Atlantic*, in an article entitled "The Nearness of Animals to Man:" "Tame honey-bees have ceased to make comb since the apiarist has begun to furnish them with a good manufactured article." But where, I wonder, did the author find his authority for the rest of it, and for certain other affirmations quite as startling? For instance, speaking of the rearing of queens, "In order to provide for emergencies, several larvæ are reared in a single cell, which the old queen is never permitted to approach, since she is as jealous of these royal scions as was ever Persian padishah of his next of kin. For this reason they are kept in close confinement until they are needed."

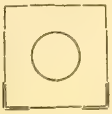
The article is extremely interesting, but it must be confessed that the author's bee-lore slightly impairs one's confidence. One can not but wonder what proportion of the whole is truth. NELLIE LINSWIK.

[You have had most excellent results in wintering; but is it not possible that you might have done a little better by having a larger entrance and a sealed cover? We hope that, for the sake of experiment, you will try two or three colonies next winter. So far our observation leads us to believe that sealed covers offer special advantages during the *springing* of the bees.

We become almost discouraged sometimes when we note how the Wiley lie still bobs up its head here and there in standard periodicals; and how such nonsense about bees as appeared in the February *Atlantic* could be inserted is beyond our comprehension. We know that it is almost impossible for an editor to compass all knowledge, and therefore to judge in regard to the accuracy of all statements made in sundry articles that pass through his hands; but why in the world can they not sometimes submit some of their so-called "science" to specialists? We hope that bee-keepers all over the land will send in a protest to the editor of the *Atlantic Monthly*, published in Boston, Mass. *We* shall certainly do so. The more bee-keepers there are who will take the pains to do so, the more effect it will have. We must not let such absurdities go unchallenged; and letters of earnest respectful protest from three or four hundred bee-keepers will have more effect than the protests of a dozen editors of bee-journals.

THE D. CASE—SEE GLEANINGS, PAGE 248.

Thanks for your naming the single case for me. Allow me to say that I now use a tin folded like this, L, put on the outside of the case, nailed at each end with a single ½-inch nail, with a string or wire around the middle of the case, which holds the tins snug in place to the sides, and the sides solid to the sections. When a string is used, better wax it where the bees can get at it, or they may gnaw it off.



SEALED COVERS PREFERRED.

Tell Dr. Miller I have been using tight sealed covers 20 years; in that time, I have tried porous covering 8 years on a part of my bees, by which I lost hundreds of dollars. Sealed covers as the bees prefer it is my way.

F. DANZENBAKER.

Washington, D. C., April 16.

ABSORBENTS VS. SEALED COVER.

As you have been advocating sealed covers I thought I would tell how my bees have wintered with absorbents. I put an even 100 colonies into winter quarters last fall in the home yard. They had a good flight early in March, and began breeding rapidly. To-day there are

97 booming colonies, and they are getting pollen quite freely. I use a support over the frames similar to Hill's device, and a crate with cloth bottom, filled with chaff and sawdust, instead of chaff cushions. Your sealed covers may be all right. I do not say they are not; but as long as I can winter bees with absorbents with a loss of only 3 per cent, just so long I am going to have upward ventilatiion.

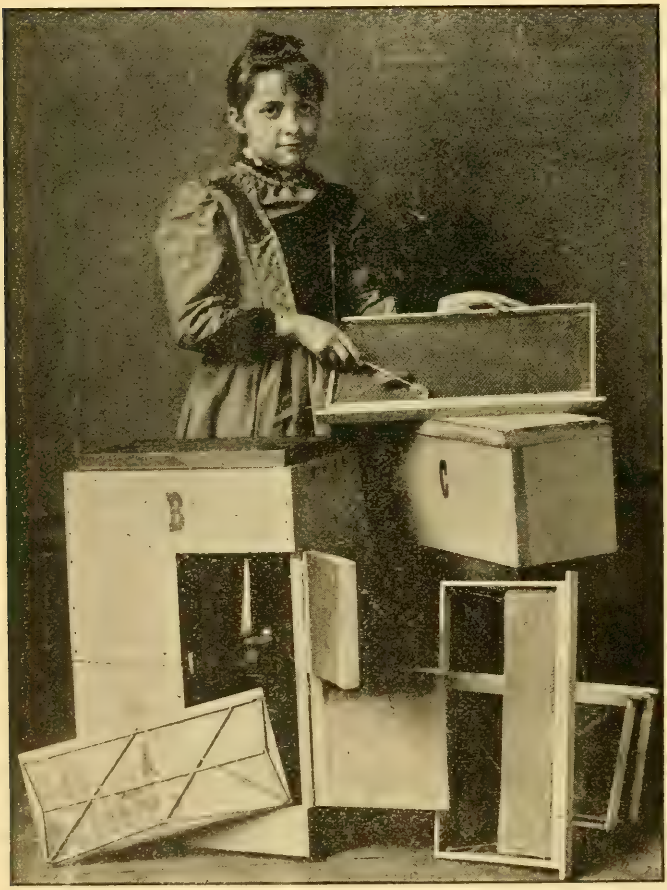
W. G. LARRABEE.

Larrabee's Point, Vt., April 8.

WIRING FRAMES.

J. A. GOLDEN'S PLAN.

Friend Root:—With your permission I should be pleased to present through GLEANINGS, to the bee-fraternity, my method of putting foundation in wired frames. To understand fully my method I send you a photograph, with explanation (how to do it, and be happy while doing it). I am aware that several devices have been invented, and some of them have worked fairly well; yet a tedious task and dissatisfaction is the result generally; while, if my mode is followed as herein explained, it will undoubtedly give the best satisfaction of any device ever presented to the bee-fraternity for the above purpose. We therefore take it for granted that the successful apiarists have systems all along the line of the various manipulations. By this class my device will be greatly appreciated; and now, friends, after you have looked at the accompanying picture of my device, don't think that you can perform perfect work on your first or second trial. You will soon learn that the press-board, or die, must not be too hot, however. A little practice is requisite as with all other devices, after which success will be the result.



GOLDEN'S METHOD OF PUTTING FOUNDATION IN WIRED FRAMES.

If Dr. C. C. Miller adapts his diagonal perpendicular style of wiring to my method he will make each frame a duplicate of each other. Thus, a board half an inch thick is cut out to fit your frame inside; cleats are nailed on one side to keep it from warping. Place this board in one of your wired frames, and, with pencil, mark each wire of your frame. With a saw, make incisions an eighth of an inch deep, and the same in width. Get a strip of iron one eighth by one inch wide, and, with a sharp cold-chisel, split it into three strips; then with a file dress them to one width. Cut them to suit the kerfs of your board; file notches at suitable places in each piece, so a medium small wire will lie in the notch. Place each piece in place, and, with a slim awl, make a hole on each side. At the notch a wire is put through, then with pliers twist the two ends, making the dies solid. See board A.

The heater, B, is a box 12x18 inches at bottom, 9x17 inches at top, and two feet high. All the above is outside measure. Several fourth-inch holes are made at top and bottom for ventilation. A sheet-iron top is made similar to a dripping-pan, 1½ inches deep, with a flange to nail on top of box B. The iron is perforated thoroughly to avoid warping when heated by a lamp which is used for this purpose. See box B. The foundation-stand, C, is a box six inches high. It fits the inside of your frame, with a groove cut at one top edge for the comb-guide to rest in when the frame is placed on the stand or box. Insets are cut where each wire-nail hook comes, so the wire will strike its full surface, and evenly over the foundation comb. This stand should be covered with a piece of oilcloth, with canvas side out, tacked on and kept quite damp, to keep the foundation from sticking, as it often does.

The comb-guide fastener, D, is a cog-wheel about an inch in diameter, molded of babbitt metal, or it can be filed out. The cogs are made beveling; the wheel is fastened to a metal handle, the beveled side of the wheel next to the wired sheet of foundation when in use, thus leaving the edge of foundation, after fastening, cell-shaped, and perfectly fastened. Please observe little Foda in the act of fastening the foundation to the comb-guide.

HOW TO PROCEED.

A lighted lamp is placed in box B. The press-board A is placed on the heater B, with metal dies down, and heated pretty warm. In the meantime place a sheet of foundation on the stand C, and then the wired frame over the foundation, pressing it down so the comb-guide will fit down well into the rabbet cut in the edge of the stand C. Now lift the press-board from the box B by two small cleats previously tacked across the back of the board, and place the same in the frame on the stand C. The metal dies press the small wires into the foundation, and at the same time melt the wax sufficiently to attach firmly the wire to the foundation. After a number of frames have thus been treated, heat the wheel D and finish the lot all at one heating. The frame containing the half-sheet, as you will notice in the engraving, is Root's extra thin surplus foundation. Friends, try it. J. A. GOLDEN.

Reinersville, O., Jan. 1.

[We have no doubt that you may be able to imbed the wires into foundation as you describe; but a far simpler way is, to heat those wires by running a current of electricity through them. See editorial elsewhere.]

PREVENTION OF SWARMING.

PUTTING A PERFORATED ZINC HONEY-BOARD UNDER THE BROOD-FRAMES; RESULTS.

A friend in Missouri, working on the problem of preventing swarming, asks my opinion of the following plan: Put a queen - excluder under the hive, having plenty of space under the excluder for the exit of the bees. Of course, no queen, young or old, could get out of the hive; and if the excluder is put under at the beginning of the clover harvest no swarm would escape, because no queen could go with them. Or, if a swarm were wanted from the colony, the excluder might be put under after the issuing of the prime swarm, thus preventing the issue of an after-swarm. Putting an excluder under is one of the things I talked over last fall; and while there are very serious difficulties in the way, I'm not so sure that it is not possible some use might be made of it. The two serious difficulties are, first, that all the drones would die in the hive; and, second, that no young queen could leave the hive for fertilization. Let us see how it would work. Suppose a prime swarm issues. The queen, not being able to leave the hive, the swarm is likely to return; but in some cases it might go into another hive or unite with another swarm. If, however, all hives in the apiary had excluders under them, there could be no real loss. Generally, though, the swarm would promptly return; and while in some instances the cells might be destroyed and the colony continue with its old queen throughout the season, the great probability is that the old queen would be killed on the hatching of the first young queen, if not before. I don't know just what would be done next; but I suspect that, no queen being able to leave the hive, all but one would be killed in perhaps two weeks from the issuing of the prime swarm. Then the remaining young queen would be a drone-layer if she laid at all. So it will be seen that the scheme can end in nothing else than the ruin of the colony.

But, can no use whatever be made of it? The first difficulty might be got over by taking Doolittle's plan—a plan that looked troublesome to me at first, but I'm not sure that it is not the least troublesome way, in the long run, of getting rid of drones. The plan is, to have no drone comb in the hive except perhaps an inch square in one comb; then when the drone brood in that patch is ready to hatch, slice off their heads, and repeat the slicing once in three weeks. Even if a very few drones should be hatched in other scattering cells, they would be torn to pieces after dying and would do no great harm.

But the other difficulty is more troublesome. True, the destruction of the old queen is not so serious a matter, and we could stand that well enough if we were sure she would be followed in good time by another laying queen. But that queen must be fertilized. Now, if my supposition is correct (that only one young queen would be left living in the hive), and if we could know just when that interesting consummation would occur, then we could take out the excluder and all would be lovely. But, alas! the ifs. We could not afford to go through the hive every day to see if the proper time had come to take away the excluder.

But it wouldn't need watching every day. How often would be necessary? Before finding out, we need to know two things that at present I don't know, but they might easily be found out. First, how long after the hatching of the first queen may we count on having only one young queen left in the hive? and, second, what is the earliest period after hatching that a young queen will be too old to be fertilized? or, in other words, how long may we keep a young queen confined without spoiling her chances for fertilization? I do not know this; but careful observation might easily determine it. A virgin queen sent to me from England when six days old was ten days on the way, and was then fertilized, and laid all right. So she must have been sixteen days old or older when fertilized. If she stood the confinement of the ocean voyage, would she not stand, at least as well, confinement in the hive?

Suppose, now, we put the excluder under before there is any danger of swarming, or at least make sure that eggs are in the hive when the excluder is added. Then we are safe in leaving the hive untouched for two weeks; for if we found eggs there, there was no young queen present—at least, I *think* that is correct. So, if we open the hive in two weeks we should never find in it a virgin queen too old to be fertilized—all the time supposing that every queen may be fertilized if confined till 16 days old. Then we might count ourselves all right throughout the summer, by looking into the hive once in two weeks, so long as we found eggs in the hive.

But if working for comb honey, I should not expect very long to find eggs in the hive after the time for swarming came. Suppose, then, that, on examination, a colony is found in which no eggs are present, and further examination reveals the fact that not only has a young queen hatched out, but that all the young queens have either hatched out or have been destroyed. If, indeed, several queen-cells should be found vacated, I should not feel so very anxious about there being any danger of swarming, and I think it might be safe to remove the excluder until the young queen was fertilized, or perhaps for the rest of the season.

Suppose, however, that one or more queen-cells are found with young queens in them, and a young queen probably free in the hive. It will not do to take away the excluder; and the question arises, How soon will it be necessary to make another examination? or, in other words, how long can we leave the excluder without danger of the young queen becoming too old to be fertilized? To know this, we need an answer to the question I have already mentioned, as to the length of time after the hatching of the first young queen before the workers give up the idea of swarming and allow all the extra queens to be killed. I wonder if it might not be safe to say that all would be killed within a week after the first young queen hatches. If so, then all we need to do is to look through the hive a week later if there is a plurality of young queens in the hive.

So on the basis that our suppositions are correct, we might agree to put excluders under, only to be removed when all young queens but one were destroyed, making an examination, once in two weeks so long as we found eggs in the hive, and once a week if eggs were lacking. But I am not very sanguine about all this. In the first place, our suppositions may not be correct; it may turn out that some young queens become too old to be fertilized before they are 16 or 17 days old; and it may be that a plurality of young queens may be tolerated in a hive longer than a week. If so, then the time of looking through the hive would have to be modified, and it is possible that so great a modification would be necessary that too much labor would be involved to leave any value in the plan. Besides, there are so many ways in which disappointment may come unexpectedly that only repeated actual trials with the bees can determine the matter.

After reading over to my assistant what I had written, she said, "But there is one difficulty that you haven't mentioned, and it's perhaps the most serious one. Will your excluders always exclude?" I very meekly replied, "I don't know." C. C. Miller.

Marengo, Ill., April 13.

[You have figured out, doctor, just about what a bee-keeper will find in practice with an excluding board between the brood-nest and the bottom-board. We have tried just that very thing; and the result was, that it would be covered with dead drones to such an extent in a week or ten days in the swarming season as almost to prevent the bees from passing in and out. You can prevent swarms from absconding; but that prevention means the killing of the old queen and the non-fertilization of the virgin queens following. While it does prevent the bees from running away, it does not check that *longing desire* to swarm; and when bees want to swarm, and can't, they will waste valuable time during the height of the honey season doing next to nothing. Perhaps some of our readers will remember some of our experiments along this line, as described in Gleanings two or three years ago, at our basswood out apiary.]

BEE-KEEPERS' PHOTOS.

HIVE-CARTS AND OUT-APIARIES.

While perusing some numbers of Gleanings last fall, and admiring your supplement containing cuts of so many prominent bee-keepers, my son suggested that it would be a good plan to cut out and paste on a card each face, and then insert them in an album for convenience, preservation, etc. I found, however, this was not practicable, as it would result in the mutilation of some of them, and also their biographical sketches, etc. I then and there resolved to ask you to present your readers with the faces of all now in your possession on a sheet of paper printed on one side only, with a short sketch of each below, so that we could carry out our proposed plan; or, if you choose, to print them on a separate card would be still better, and a small charge made for those desiring them.

Well, now, you see what delay means; for has not Mr. Hutchinson gone and done it, only in a trifle different manner, and now furnishes, as far as possible, a picture of his correspondents with each article contributed? It is scarcely necessary to add, almost every one thinks this a step in the right direction, including, of course, yourself among the rest.

BOARDMAN HIVE-CARTS.

Carts *a la Boardman* are a good thing. Yes, I am sure of it, at least for me. I now have one; and I like bee-escapes, honey-boards, properly spaced frames, etc. It is going to save time and backaches in this era of poor seasons and improved migratory bee-keeping. Each one will have to vary the construction of such a cart to suit himself, and this I have done without materially altering its appearance. I have some reasons for preferring it wide enough to lift a Langstroth hive by its ends instead of its sides; among others, my preference being in favor of placing the hive on the cart the same as on the wagon. Again, there is sufficient room for lifting two hives instead of one or two top stories or even a brood-chamber and a top story as the case may be, and carting both away at the same operation. The arrangements attached to the lifting-arms are not exactly alike for lifting off a top story and carrying a brood-chamber; but both are very simple, the only addition to any hive in use being the nailing on of a wooden cleat ⅜ inch square by 8 long, either to the sides or ends, as one chooses.

This cart is expected to assist me greatly in moving hives to and from the wagon, while moving the bees to the out-apiary; yes, I mean to take it right along with the team, by simply fastening it behind the wagon, so that it can be utilized, both loading at home and unloading in the orchard at the point of destination. I can also run around and pick off top stories when once cleared of the bees, by the escape system, and have lots of fun too.

MOVING TO OUT-APIARIES.

This brings me to the last part of my article; viz., moving to out-apiaries. Many have been the methods devised and illustrated in Gleanings for moving hives containing loose hanging frames; but the simplest and most expeditious way for any one not having very rough roads nor long journeys is to use a frame covered with wire cloth, the ends of said frame having a wire nail driven through from the top sufficiently far to penetrate each frame in the hive (say ⅛ of an inch), so that, after adjusting the screens, a little pressure will soon secure all the frames at once. I have moved bees many times without a single mishap to any of the hives themselves, except that I once smothered eight colonies on a warm day in June, notwithstanding the whole top of the hive was covered with a ⅞ rim as described, so that now I am a little skeptical in regard to so little ventilation being given as advocated by some, even in cool weather, unless a large space is also given for the bees clustering in.

The tying method given by you in Gleanings some time since is the only other thing necessary for expeditious work with such a hive, having tested and used it successfully not only with a single-story hive having a loose bottom-board, but with a two-story hive as well; consequently I use it with as much assurance now as any other thing or system I know of practical value in the apiary.

F. A. Gemmell.

[Hutchinson's scheme of having a small portrait of the writer at the heading of most of the articles for the *Review* is a good one, and since he has done it so admirably it will not be necessary for us to print a separate sheet giving a short sketch and portrait of some of our contributors; in fact, we already have practically that same thing in the last form of our A B C of Bee Culture. -Your hand-cart will no doubt be a good thing. The idea of having it tag on behind the wagon when going to and from out-apiaries is a good one.]

PROPOLIS ON T TINS.

HOW TO CLEAN IT OFF WITH CONCENTRATED LYE.

When we commenced work in the shop, the first super I filled with the nice clean sections, I looked at the T tins all covered with propolis and thought to myself, "If we are to have sections unstained by propolis it will never do to put them on these dirty T tins. But, oh dear! it will be an endless task to scrape them all. I can never do it." Just then a happy thought struck me. Why not boil the propolis off? Sure enough, why not?

I repaired to the kitchen, placed the wash-boiler on the stove (one we use for such work), filled it with water and T tins, then went back to the shop to work, and left them to boil at their own sweet will, delighted to think I had such an inspiration. In about an hour I went back to the kitchen to see how my T tins were progressing. I fully expected to see them all nice and clean, and was most bitterly disappointed to find that they looked even worse than they did when I put them in, as the propolis was more evenly distributed all over them.

I next tried scrubbing them with a broom in the boiling water, but it would not work. I meditated awhile, then concluded I would try concentrated lie, providing Dr. Miller did not object. I did not know what effect the lye would have on the tins. He said I might try it. I put the boiler back on the stove to try once more. I did not feel quite so sanguine as I poured in part of a can of concentrated lye.

I did not leave it this time, but anxiously watched to see what effect it would have. It brought it off pretty well, but was not quite strong enough. I put in the rest of the can of lye, and, eureka! the propolis disappeared as if by magic. I stirred the tins with the poker to insure the lye reaching all parts of them; then with the tongs I lifted them into a tub and rinsed them off with cold water, and set them up in the sun to drain, as bright and clean as when they came from the tinner's.

I filled up the boiler with T tins again, and so on, until the strength of the lye was all used up, when I turned it out, filled up the boiler afresh, and began all over again, continuing until they were all done. I used a can of lye to a boiler of water.

Every time I fill up a super with the nice clean T tins I feel more than paid for the work it took to make them so. I am pretty sure that washing-fluid would clean them almost if not quite as well as the concentrated lye, providing it were used strong enough, although I have never tried it. However, I think I should prefer the lye, as it does the work most thoroughly and does not hurt the T tins in the least, that I can see.

If you have a lot of dirty T tins I advise you to clean them in this way, and see if you are not as delighted as I was to see them come out so bright and clean. Be sure to use plenty of water in rinsing them off. EMMA WILSON.

Marengo, Ill., April 5.

THE BEE-MOTH.

ITS HABITS; WHEN AND WHERE COPULATION TAKES PLACE.

Mr. W. B. Ransom, New River, Va., wishes me to answer the following questions through GLEANINGS: If the bee-moth larva—the so-called moth-worm—spins its cocoon inside of the bee-hive, and there issues from the cocoon a female, can she lay eggs without coming out and mating, or must she do as do the queens, come forth and mate? If the latter be true, at what age does she commence to lay?

From the conditional form of the first sentence we might conclude that it is unusual for the moth-larva to spin its cocoon in the hive. On the other hand, this is almost always just where the cocoon is spun and the pupa state assumed. In accidental cases the cocoon might be spun outside. In nature, where man did not interfere, I doubt whether the cocoons would ever be found outside the hive. Indeed, in our northern climes it is imperative, often, to the life of the insect, that the cocoons be formed and the pupa stage passed in the hive. As the late Mr. Moses Quinby showed years ago, the bee-moth, unless protected by the warmth of the colony, often succumbs to our severe winters. I have proved, however, that, in mild winters, they may endure the exposure, even unprotected by the warmth gendered by the bees.

It is probable that the bee-moths always fly forth to mate, as we usually see them during the day concealed somewhere outside of though by the hives. As many are reared on combs in the honey-house, it is not uncommon to find them in this building. They are nocturnal—that is, they fly by night, and, without doubt, usually mate as they take these after-day nuptial flights. It would be unsafe to say that they never mate in the hives. I have seen both moths and butterflies in copula before the wings of the female were dry so she could fly; though usually the same species pair only on the wing. So of this species—the bee-moth—while they usually and perhaps always mate outside, it is possible that copulation may occasionally occur in the hive.

The pairing usually takes place with all moths very soon after the females fly; and, as I have said, often before her wings are so dried that she can fly. I am sure that the bee-moth is no exception. With all insects, the females are able to "bide their time." The queen may await a pleasant day or the coming drone. Moths that usually meet the males as soon as they can fly, in case no males are present, may wait for days. This is true, also, of the bee-moth. She may wait *nolens volens*, for a suitor must come before he can be accepted. Egg-laying commences, often, the very next day after pairing occurs; always very soon.

Agricultural College, Mich. A. J. COOK.

FEEDERS.

THE TWO THAT I PREFER; HOW TO MAKE.

This spring a good many of my colonies are short of stores. I have been experimenting on feeders. Nothing in the price lists suited me. I wanted to feed early inside of the hives, without disturbing any honey-board or quilt, as I do not like to break the sealing before warm weather. Some of my hives have honey-boards with a ¾-inch hole in them. Others have quilts with dry sawdust packing on top. Now, my feeders must be simple, cheap, adapted to feed without removing covers; must kill no bees nor waste feed. I have two that fill the conditions.

and I like them better than any thing I have seen yet. The first is a quart basin of cheap stamped ware with a 1¼-inch hole cut in the bottom, into which a tube is soldered. The top of the tube comes to within ½ inch of being even with the top of the basin. Now open the hole in your honey-board, or remove packing and cut a small hole in the quilt, over which place the basin so that the bees can come up through the tube. Make a tube of coarse paper and push it into the tin tube to aid the bees in climbing up. Fill the basin with syrup as far as the top of the tube; place a float of cloth or any thing to keep the bees from drowning. Now cover the basin over with paper and make it as warm as you please with packing. The bees will come up and take that feed in cool weather, and no openings have been made to allow the much-needed heat of the hive to escape.

The other feeder is made in this way: Take a Mason quart jar. Break the porcelain lining out of the cover; punch a dozen or more small holes in the cover with an awl. Now get a piece of pine board, ⅞ by four inches square; with an extension bit bore a hole through it large enough to receive ¼ inch of the top of the jar. When the cover is on, fill the jar with thin syrup. Screw the perforated cover on tightly; place the block over the hole in the honey-board or quilt; insert the jar and insert in the block; replace packing, etc. The bees will suck the contents out of the jar in one or two days, though of itself it will not run out. I think this is an improved method of using the Mason jar as a feeder. Of course they are cheap, as you spoil only the covers, and every one has empty Mason jars not in use at this season of the year.

Many feeders are recommended that are not fit to use. Wooden butter-dishes leak, and the syrup goes to daub up the packing. They are nice to have in an apiary to save an occasional piece of broken honey, but are of little use as feeders except in feeding candied honey. In this case, make a hole in the dish and use the same as the basin described above. Gray's feeder is not good, as it kills bees to some extent.

H. LATHROP.

Browntown, Wis., April 9.

[Your circular feeder—that is, the first one you describe—is very similar in principle to the very excellent Miller feeder. We have no doubt that it will work very nicely. The second one is nothing more nor less than a slight modification of the old-fashioned pepper-box feeder that we have sold for so many years. We believe that it was E. France who first called attention to this feeder, and it is by him used very extensively, even at the present day.]

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

MRS. HARRISON IN FLORIDA.

Mr. Editor:—It appears strange to one who has always lived at the North, to see plants blooming so differently from what we have been accustomed to. Fruit-trees do not blossom all at once, but continue to bloom for a long time. There will be peaches upon the trees, the size of peas, and plenty of blossoms at the same time. The peen-toos commenced blooming in October. Since the 9th of January I have noted peach-trees blooming, and there are some late ones to bloom yet.

Bees appear to be doing well, and commenced swarming April 1. They are gathering honey from orange bloom, tie-tie, dewberry, spiderwort, and many other flowers unknown to me. What surprises me the most is, that goldenrod is out in full feather. Inclosed is a sprig of it. Bees in this town have only half a flight, as half of it is the bay. There are not many colonies kept here, and all that I have seen are blacks.

I leave here in a day or so, en route for the North by the way of Wewahitchka, to visit the noted orange-groves and large apiaries located there. I long for home, and to see GLEANINGS, which I have missed for some time.

MRS. L. HARRISON.

St. Andrews, Fla., Apr. 11.

SULPHURIC ACID IN WAX-RENDERING; HOW TO PROPORTION THE WATER AND ACID.

Will you please state in GLEANINGS, in plain United States, how many spoonfuls of sulphuric acid should be used to a gallon of water when rendering old combs. Some one has stated it once in milliliters; but Dago is incomprehensible to the average American. Does the use of the acid injure the tin vessels in which the wax is rendered? Must the combs be soaked in the solution some time before boiling, or can we simply pour the acid into the water, throw in the wax, and start up the fire?

Newhall, Cal., March 26. WM. G. HEWES.

[The proportion of acid that we have recommended is 1 lb. of acid to 4 pails of water. This would be reducing the acid about 100 times; 1 lb. of acid means 1 pint; 4 pails would make about 50 quarts; 1 drachm is equivalent to about 1 teaspoonful. Therefore in 1 gallon there would be somewhere about 1000 drachms or 1000 teaspoonfuls. According to our proportion you would want to take about 10 teaspoonfuls of acid to a gallon of water; but you must remember that the acid will attack the spoon unless you dip it in melted wax, and then you will destroy the proportion, because the spoon won't hold as much. To get the matter correctly, measure ten teaspoonfuls of water into a glass tumbler; make a note of the water-line; pour out the water, and then fill up with acid to this water-line, and then this you can put into your gallon of water and have the proportions about correct. It will do no harm to increase the amount of acid, providing your wax is very dirty. We sometimes make it in proportion of from 1 to 50 and 1 to 75. It depends on how much dirt there is to be clarified out. Use a kind of stone crock that is used for cooking; pour in your water and then the acid, and then your refuse pieces of wax. Let it boil over a slow fire for a couple of hours. Move it back on the stove, and keep it just barely hot for about five hours. This will allow all impurities to settle. At the end of this time dip off the wax. Be careful not to stir it up too much.—Yes, the acid before dilution, and to a proportionately less extent after, will injure tin utensils. Wooden or crockery ware should be used. No, the combs do not need to be soaked before heating the acidulated water.]

IN FAVOR OF ABSORBENTS.

Ever since you have been agitating sealed covers I felt prompted to write. Such an article as friend Dadant's ought to carry conviction with it. I have had bees for 7 or 8 years; have wintered 40 stands some of the time, and—well, a little fishy—but I have never lost a single stand by being poorly wintered—have never lost more than four or five from *any cause during* the winter in all this time. Those were queenless, or something of that nature. I live ten miles north of Terre Haute, Ind., and have had some pretty bad winters on bees here too; but I have never used sealed covers. Perhaps one is occasionally sealed; but a very large per cent, at least 90, have had more upward ventilation than I wanted, on account of poorly constructed hives. I *always* use something similar to the Hill device—a piece of burlap spread over the top of the device and the bees, and then fill in—not full if a two-story, but full or nearly full if a 1½-story—with old cloths, cotton or woolen, old carpet, etc. G. F. AYRES.

Atherton, Ind., April 8.

HOW TO CATCH ROBBERS WITH A PORTER BEE-ESCAPE.

During the drouth last fall I had some trouble with robber-bees; and after trying several plans to prevent, I have settled upon one more way of "heading off" the little rogues, and am not quite satisfied that I am right, hence this letter to you. When the robbers begin another run on a hive, I propose to plug the entrance with a Porter bee-escape to point in; remove the top of the hive and quilt, and substitute double wire cloth (wire about one inch apart), and let robbers and all run in, and *keep them there* a few days. What do you think of the scheme? If all right, how long should I keep them cooped up before opening the hive?

MRS. A. R. FORMAN.

Slatonville, Ark., Mar. 15.

[The scheme will be excellent; and although this same thing has been proposed before, we do not remember that any one has tried it. We should be glad to have you and others try it, and then report. It will catch the robbers; and if they can't get out to tell the rest of their comrades, they can't get up a very big robbing.]

KEENEY VS. THE HORIZONTAL WIRING.

In GLEANINGS for 1890, page 371, Mr. E. D. Keeney gives his new way of wiring to which the members of the Root establishment seem to have taken a liking at once. Ernest has proposed wire nails, to be used in place of the staples in Keeney's plan, these nails to be bent to a hook. This was a great improvement. On page 561, friend Hatch makes another important improvement on Keeney's plan, to which Ernest says: "I like your improvement on the Keeney method." On page 557 he says to Keeney: "Your method of wiring is working nicely, and it will probably supersede all others." Now, why is this method abandoned, and the horizontal method by piercing end-bars recommended? Has it proved a failure? With me the former is done more rapidly, and gives, so far, good satisfaction. S.

Klona, Iowa, March 9.

[The Keeney wiring as improved by Hatch did not prove to be a failure. With heavy or medium brood foundation it worked very nicely; but it would not work satisfactorily with light brood. The latter grade as you may know is considerably cheaper than either of the other two, and as this works nicely with the horizontal wiring we gave it the preference. It is less work to wire on the horizontal plan; our girls who wire many hundreds of frames will vouch for this. Again, the Keeney plan did not please all, because the foundation would bulge in places. We recommend the horizontal plan in a word because it is cheaper, not only in time of wiring but in the grade of foundation that can be used with it. It should be remembered that the horizontal wires should not be drawn too tight, otherwise the foundation will bulge.]

THAT "KING BEE" AND THE RAMBLER: AUTOMATIC SWARMERS AND HONEY ADULTERATION.

I am glad the "King-bee of the Home" is safely hived again. I have greatly enjoyed my imaginary travels with him. I expect to draw my head within the shell (clam) if I find he has any idea of coming this way. While we Minnesota bee-keepers are a fine and distinct race for pure product, we don't want any of our patents and methods of operating interviewed by any one not "in it." They could not understand the situation, seen through their Kodak.

If that Rambler should ramble through here I shall turn my 200-lb. "*bunt sheep*" (thoroughbred Oxford) loose on him; and his business set up will beguile leisure hours for GLEANINGS readers for a whole fortnight.

I hope you will try to help us all you can to get an automatic swarmer successfully at work. It will be a wonderful help to single-handed folks who till the soil and cultivate the bee. I must have some by June if I can.

Regarding adulteration, my brother writes me that, when at work in canning-factories in California, all their jellies and all their extracted honey put up where he worked was three-fourths glucose. He said he never was so surprised, for he thought where such a supply of pure product was obtainable such things as adulterants were never used. This is a fact, Mr. Root, and I hope you will use every effort to expose and stop the frauds.

Faribault, Minn., Mar. 24. L. J. PAGE.

[We are not willing to let the matter stand right here. Can not affidavits, or such evidence as will be recognized in courts, be procured to convict these adulterators? Will your brother take oath to such statements? and if so, let's test the law in California. We should be glad to get legal advice from some one of our subscribers in California, of the law profession.]

QUEEN - EXCLUDERS FOR EXTRACTING: HOW THEY WERE PLUGGED UP WITH PROPOLIS.

As I saw a statement from Mr. A. Sion, Kyle, Texas, about propolizing perforated zinc, I will tell you what happened to me last spring. Just in the beginning of basswood time I put on 20 zinc excluders; left them on one week; and when I looked in the upper story there were hardly any bees up there. I thought they might be too weak, so they would not work in the second story; but when I lifted the zinc up I found they were strong, but they would not go through the zinc; and some had almost all the holes filled up with propolis. As soon as I found it would not do I took them all off, and I got about 3150 lbs. of extracted honey from 30 swarms; but my idea is, that, if I had left them on I should not have had 10 lbs. apiece. I think they are great queen, bee, and honey excluders in our Western country. I will try a few this season again. WILLIAM SEEMANN.

Boscobel, Wis., Mar. 27.

[This seems a little remarkable. It makes, however, only the second report of this kind. All others, so far as we remember, declare in favor of the zinc. J. F. McIntyre, of Fillmore, California, uses it largely, and recommends it to his bee-keeping friends. We presume your bees were working on the sealed-cover idea. While the fact that honey began to be stored *after* you removed the excluders is suggestive, it may have been only an accidental coincidence. It is possible that the honey began to flow in about that time. If bees don't have much to do they will plug up with propolis; but if there is a good flow of honey they do not bother much with gumming. It looks a little as if, when they stopped up the zinc holes, little or no honey was coming in then. J. A. Green suggests that such rare instances are due to poor covers. Bees, to store comb honey, must have their receptacles thoroughly well sealed over.]

ORANGE-BLOSSOM HONEY; HOW THE NEW COWAN REVERSIBLE EXTRACTOR COMPARES WITH THE NOVICE.

Your new reversible extractor, the "Cowan Rapid," received a few days ago, works nicely. I have thrown out the last 100 gallons with it, and I must say it is a boss machine. The sample of honey sent was drawn right from the machine. We don't have honey much thicker than that here. A Novice machine would hardly throw it out as clean as the new one will.

THE BEE-ESCAPE, AND HOW IT SAVES LABOR.

Some question the practicability of the bee-escape. I have used them a good deal, and pronounce them a good thing. They have no faults if you understand how to use them. There are several good makes. I like the Porter. With 20 of these, one day last week I took 1000 pounds of honey with 45 minutes' labor—15 in putting the escapes on in the evening, and 30 in taking the honey to the extracting-room the next morning. Can one man remove the same amount of honey by any other method in the same time?

It might not be out of the way to say that those same 20 colonies each gathered from 8 to 10 pounds of honey the day the honey was removed. Would they have done this if the old method of shaking and brushing had been used? I say no.

Our spring flow is at a close, lasting only about 10 days; but it was good while it lasted. My scale hive (on average colony) averaged about 10 lbs. per day. One picked colony gained 17½ lbs. in 9 hours. How's that? Will the man who says "orange" does not yield honey please walk up? A. F. BROWN.

Huntington, Fla., April 12.

ANOTHER METHOD OF PRODUCING WAX SHEETS.

Did you ever try dipping wax for foundation with a glass vessel filled with ice water? My son is a dentist, and to-day he is preparing wax (for taking impressions) into thin sheets about the same as for foundation. Sheets so prepared are very smooth and nice. Any glass vessel six inches in diameter would make a sheet 18 inches long, and as wide as the bottle or vessel is long. The cold water cools, and causes the wax to adhere at once; and from what I have seen this morning I think he could produce one sheet per minute. Perhaps this mode is not new to you. If it is, try it on a small scale, and see if it will not beat wood all together.

Kenna, W. Va., Mar. 22. FRANKLIN GARNS.

[We have never made sheets in the way you describe, but have no doubt it could be done in that way. We simply dip thin boards of the right size into melted wax, and then plunge them into ice or cold water. We can thus make the sheets much faster than one a minute.]

ITALIANS GATHERING TWICE AS MUCH HONEY AS BLACKS.

I notice some of the bee-keepers prefer black bees to the Italians. Well, they can take them for my part. I have both blacks and Italians, and I say positively that my Italians gather twice the honey per colony that my blacks do. I will admit that the cappings on the sections taken from my blacks are a little whiter, when they have any, which is not often the case.

Lexington, Tex., Mar. 23. WM. DOUGLASS.

ANOTHER SCHEME FOR TOP-BARS.

Mr. Calvert:—Below see two ways of avoiding lateral motion in top-bar of frames. First, cut a notch on the under side of the projection of the top-bar $\frac{1}{32}$ or $\frac{1}{16}$ deep, and ⅛ wide; or, second, let the bottom-bar project within $\frac{1}{16}$ of the side of the hive. I find if a hive is cut like No. 2 no tin rest is needed. R. T. W.

Little Britain, Canada.

Fig. 1

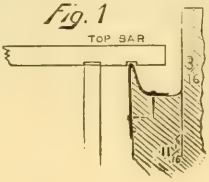


Fig. 2

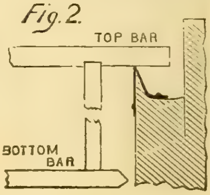


[We have no doubt that your scheme would work very nicely, Mr. R. T. Whatsyername; but the first thing you would encounter would be the change in the length of the top-bar, and that seems almost out of the question—at least, any radical change on standard sizes. There would be an advantage, however, in having a bee-space around the ends of the top-bars as well as around their sides; but practical bee-keepers seem to prefer the top-bar run clear up to the end of the rabbet.]

AUSTRALIAN BEE-KEEPERS AND WHAT THEY PROPOSE TO DO AT THE WORLD'S FAIR.

The bee-keepers of New South Wales are just arranging for a conference to be held at West Maitland, in this colony, and to forward an exhibit to your Chicago exhibition. Our paternal government is taking the exhibition affairs up in good earnest, and the colonies should be well represented. I hope to go over and see a small portion of America in 1893. We have heard so much about it that one feels quite anxious to see such a wonderful country. C. F. JEANNCRET.

Hunter's Hill, New South Wales, Feb. 16.

[Good for Australia and her bee-keepers! We always thought your people were progressive. We shall be glad to welcome you, and hope you will come so as to attend the North American convention, which will be held at the World's Fair.]

OLD FOUNDATION, AND HOW TO RESTORE IT.

On reading J. A. Green's article on page 239 I was anxious to see whether any process would be mentioned by the editor whereby old hard foundation may be restored; but I see that no remedy was suggested. I have a friend, a bee-keeper, who says that, by dipping in warm water, foundation, no matter how old and hard, can be brought back to its original quality. This is an important matter. I should like to hear from others on this subject.

Browntown, Wis., April 9. H. LATHROP.

THREE LAYING QUEENS IN THE SAME HIVE.

I have a hive with three laying queens in it, and all the bees pass in and out through the same entrance. Let us know how many times you ever had the same thing. I have tried, this spring, Doolittle's process of raising queens, and find it works well. I got some queens, but not a single drone? What will the harvest be?

Providence, R. I. C. H. PEABODY.

[We never had three *laying* queens in a hive at one time, but several times have had two. We do not remember that any one else has reported that many at a time, though we have no doubt that it has happened many times.]

NOTES OF TRAVEL

FROM A. I. ROOT.

SOME KODAK VIEWS FROM REGIONS ALREADY PASSED OVER.

If you will turn to page 172 of our issue for March 1 you will find, where I was describing the mountain stream through the canyon near friend McIntyre's, I used these words: "The stones, big and little, have been tumbled and rolled by the water for so many ages that most of them are beautifully rounded and polished; hence it is all the more risky clambering among them. In places the water comes down so steep that it is really a succession of rapids. The water of these mountain streams is usually beautifully clear, pure, and cool." Well, the rocks and the water, as it rushed and boiled and sparkled through the pebbles little and big, made such a fascinating picture to me that I resolved to try the Kodak on it. Below you see the result.

A VIEW FROM A MOUNTAIN CANYON NEAR FRIEND M'INTYRE'S.

Some of the stones are beautifully white, as you see; others are colored. Some are comparatively soft, while others are like flints, and a few are like jasper and carnelian. Where the water is pure and soft, the rocks are usually clean. That is one reason why I love soft-water springs and rivulets. They leave no deposit of chemicals on the sticks and stones, to make every thing slimy, discolored, and untidy. As there is a great demand for pure water for drinking purposes, these soft-water streams down the mountain are hunted up and piped many miles. The nights in California are cool, especially in the winter time; therefore, although it may be quite warm in the middle of the day, the water coming down these shady canyons is almost always beautiful for slaking thirst; and the abundance of it, so fresh and pure, adds much to the exhilaration. The picture gives you something of an idea of how it boils and sparkles and babbles—a babbling brook truly, but on a rather large scale, as you may find to your sorrow if your foot should happen to slip on one of those polished stones.

I told you that Mrs. Root followed as long as her strength held out; then she rested while friend McIntyre and I went on to explore Devil's Gate. The further we explored into the mountains, however, the more wild and weird it looked, until one began to wonder where he would end if he kept on climbing and exploring. As there was much to see, however, we decided that we could not afford the time to go any further, especially as this kind of exploring must all be done on foot, or, rather, on *hands* and feet. So we made our way back to where Mrs. Root had been left. I had just been thinking that it was almost a dangerous place for any one to be alone, when in this wild mountain canyon; and then my vivid imagination suggested, "What if some of these reckless characters away off here in California should be prowling round and find a *woman* off here alone, without anybody near enough to even hear her call?" We reached the spot where Mrs. Root agreed to wait. Sure enough, she was nowhere to be seen. We called faintly at first, then louder. No answer—not a sound was to be heard except the rushing of the waters over the stones. My heart began to beat violently. The lonely feelings came back that I told you about, and my thoughts ran rapidly from the point where we met in San Francisco up to the present time. Oh! why did I let her go out of my sight and hearing in such a place as this? While the "poetry" part of the situation was fading away at a pretty rapid rate, friend McIntyre shouted still louder, and then we began exploring around further from the point where she had agreed to stay. All at once we caught sight of her behind a rock down near the rushing waters that prevented her from hearing our voice. My anxiety and forebodings disappeared at once, even if my heart did not at once stop its wild beating, and I am afraid I began to scold because she did not keep her promise and stay where we left her until our return. Well, we got it all settled, and proceeded home. I could not leave Devil's Gate, however, without trying the Kodak once more. At the right of the picture you get a glimpse of where the sun has illuminated a corner of one of those great reddish jasperlike rocks. Mrs. Root and friend McIntyre are in the distance, and a small canyon opens up through the mountain above their heads. If a railroad should ever run up these mountains, it will open up one of the finest bits of scenery there is to be found almost anywhere. Why! it really makes me thirsty a I see that gushing stream of living waters as i sweeps by, close to friend McIntyre's feet, as you see in the cut.

SCENE NEAR DEVIL'S GATE, SESPE CANYON, VENTURA CO., CAL.

A GLIMPSE FROM THE INTERIOR COURT IN THE CENTER OF THE CORONADO HOTEL, CORONADO BEACH, SAN DIEGO CO., CAL.

We will now go back again to San Diego. I told you, three years ago, of San Diego's wonderful natural harbor, and of the motor railway that runs away out into the ocean on a thin little streak of sand, finally ending in a sort of island, or peninsula, where is situated the celebrated Coronado Hotel. For a time this was said to be the finest and largest hotel in the world. Since it was built, however, other hotels have eclipsed it. I do not know whether it pays expenses or not—I am afraid it does not; for, to get even a moderate interest on the capital invested, it would require a higher state of prosperity than the city of San Diego seems at present to enjoy. As pictures of this famous hotel have been scattered far and wide, I shall not attempt one here. Inside of the building or buildings (for it is really an aggregation of many buildings) is a court, or garden, of perhaps a quarter of an acre. There is no opening through from the outside into this garden, except through the buildings. By the way, there are stores and offices, halls for public meetings and theatricals, to say nothing of billiard-rooms and the like, all within this one hotel. We entered this inner court by passing through a drug-store. When I visited it three years ago it was the finest thing in the way of a floral garden I ever saw; yes, it indeed eclipsed every thing in the shape of greenhouses and conservatories that I have seen in any of the large cities or expositions. You see, the climate here at San Diego is such that almost every thing will grow in the open air that grows in any part of the world. Exotic flowers, such as I had never seen before, were here, thriving with wonderful luxuriance right in the open air. Humming and other kinds of birds of gaudy plumage also helped to add interest to the scene, while the thunder of the waves just a few feet away furnished music for an accompaniment. One thing that added largely to the beauty of this garden was, that trained gardeners were constantly removing not only every flower, but almost every leaf or twig, as soon as it had passed its prime. A beautiful piece of statuary stood in one corner of the garden, and innumerable fountains cast a silvery spray all round about it. I feared the Kodak could hardly do such an exhibtion justice, but I made the attempt notwithstanding, and you can see the result.

It gives you a little glimpse of a part of the hotel balcony that surrounds the whole inner court. The lower porch is not visible, but you can see the upper ones. The rooms for the guests all look in upon this tropical garden; they also look out upon the other side on the ocean where its restless waves are constantly pounding the white sandy beach as they throw the briny spray and give forth at times their deafening and unceasing roar. Every one who goes to the Pacific coast—at least all who venture near San Diego—should visit Coronado Beach and look over the great hotel. Beautiful grounds and grassy lawns cover several acres of ground around the hotel. Bath-houses, museums, ostrich-gardens, and other attractions, are to be found in the vicinity of this popular resort.

OURSELVES AND OUR NEIGHBORS.

Ye are not your own, for ye are bought with a price.—I. COR. 6:19, 20.

A little bit of a yellow-covered booklet came floating through the mails, all the way from Melbourne, Australia. On the back of it we found written, "F. Chambers, Gladstone Building, Franklin St." The book is by George Müller; and the title of it is, "Scriptural Advice to Christians Concerning their Earthly Occupation." The very minute I read the title it occurred to me that I should be very glad indeed of some advice from Müller himself on this perplexing question; hence I turned with eagerness to the first page, and read the following lines:

> The children of God, who are strangers and pilgrims on earth, have at all times had difficulty in the world, for they are not *at* home, but *from* home; nor should they, until the return of the Lord Jesus, expect it to be otherwise with them. But while this is true, it is also true that the Lord has provided us, in all our difficulties, with something in his own word to meet them. All difficulties may be overcome by acting according to the word of God. At this time I more especially desire to point out the means whereby the children of God, who are engaged in any earthly calling, may be able to overcome the difficulties which arise from competition in business, too great a number of persons being occupied in the same calling, stagnation of trade, and the like.

I read the above again and again. I have read it at the noon service, and I have read it in the prayer-meetings, both young and old; and every time I read it the concluding words seem to me like a glimpse of clear sky through the troubles that gather like clouds in regard to finance, labor, capital, etc. The special point about too many people being occupied in the same calling is one that interested me greatly. While in New Orleans there was much talk about too many people being engaged in the cotton business, and hence the low prices and stagnation. At the horticultural institute, Jackson, Mississippi, the speakers dwelt especially on this one theme; and in the North we have all heard the talk about 75-cent wheat, and the conclusion that many seemed rushing to, that "farming don't pay." What is the trouble? Let me give you a few words more from our good friend Müller. By the way, I shall have to skip a good deal; but whenever I draw the line it seems really too bad to omit what follows:

> Now, suppose the believer is in a calling in which he can abide with God, the next point to be settled is: *Why do I carry on this business, or why am I engaged in this trade or profession ?* In most instances, so far as my experience goes, which I have gathered in my service among the saints during the last forty-five years, I believe the answer would be: "I am engaged in my earthly calling, that I may earn the means of obtaining the necessaries of life for myself and family." Here is the chief error from which almost all the rest of the errors, which are entertained by the children of God, relative to their calling, spring. It is no right and scriptural motive, to be engaged in a trade, business, or profession, *merely* in order to earn the means for the obtaining of the necessaries of life for ourselves and family, *but we should work because it is the Lord's will concerning us.* This is plain from the following passages: 1 Thess. 4:11, 12; 2 Thess. 3:10 12; Eph. 4:28. It is quite true, that, in general, the Lord provides the necessaries of life by means of our ordinary calling; but that *that* is not *the reason* why we should work, is plain enough from the consideration, that, if our possessing the necessaries of life depended upon our ability of working, we could never have *freedom from anxiety;* for we should always have to say to ourselves, And what shall I do when I am too old to work? or when, by reason of sickness, I am unable to earn my bread? But if, on the other hand, we are engaged in our earthly calling because *it is the will of the Lord concerning us that we should work*, and that thus laboring we may provide for our families and also be able to support the weak, the sick, the aged, and the needy, then we have good and scriptural reason to say to ourselves: Should it please the Lord to lay me on a bed of sickness, or keep me otherwise, by reason of infirmity, old age, or want of employment, from earning my bread by means of the labor of my hands, my business, or my profession, he will yet provide for me. Because we who believe are servants of Jesus Christ, who has bought us with his own precious blood, and are not our own, and because this our precious Lord and Master has commanded us to work, therefore we work; and, *in doing so*, our Lord will provide for us; but whether in this way or any other way, he is sure to provide for us; for we labor in obedience to him; and if even a just earthly master gives wages to his servants, the Lord will surely see to it that we have our wages, if in obedience to him we are engaged in our calling, and not for our own sake.

When I first got the book I read the above extracts to Mrs. Root, as we sat together one evening, without telling her who the author was. When I had finished I said, "There, what do you think of that? Who should you judge wrote this little book?" and I held it up. She replied, "Why, I am sure I can not tell; but it evidently comes from somebody who stands on a higher plane of spirituality than the most of us do." Then when I told her that it was George Müller we both had to laugh. In very truth, Müller *does* stand on a higher spiritual plane than the rest of us; and, by the way, it does seem to me as if the great wide world—the business world as well as the Christian world—were passing Müller by, giving him and his work but little thought or attention. I once dreamed that I discovered a machine or principle for navigating the air; and I expected, of course, the whole world would stop its work and look while I demonstrated over their heads and before their eyes my new principle. I was a good deal disappointed because folks did not pay very much attention to me or to my "navigation." Some of them stopped their work and looked a minute or two, and then they went on hoeing corn and driving business as usual. In fact, a great part of them did not look up at all. They evidently felt content to stay on the *ground* and let folks navigate the air who felt that way. So in regard to Müller. He came upon the spiritual and financial world so sudden, that, for a time, it was almost startling. A few people stopped and considered the matter.

Some wondered for a while if we had not all been making a great mistake—a mistake because we lacked in faith. Müller loved humanity; at least, he did *after* the Holy Spirit made its dwellingplace in his heart. Then he began to *work* and *pray*. He believed it was not God's will that the homeless ones of the great city of London should grow up educated to sin and crime. He had faith to believe that God would furnish the means for a reformation. The great busy world looked on and concluded that it must be a string of *coincidences*, or that it was just a "happen-so," and could not last very long. But years go and come, and there are few business enterprises on earth that seem more *firmly* established than Müller's work. Now for a consideration of some of the statements he makes. A man who is industrious and diligent that he may obtain the means for supporting his wife and family, is, according to Müller, making a *mistake*. I do not suppose that he means that the above is not a praiseworthy object, and really above the heads of some of us; that is, we have people all about us who do *not* take care of their wives and children—in fact, some who neglect or refuse to provide even the necessaries of life. If these people can not be moved by any higher motive, I should most strongly urge this; but for all that, there *is* a higher plane to live on, and a higher motive for exertion. This matter of laying up something for a rainy day, or for sickness, or for old age, that is so often talked about, and so often discussed, what is it but selfishness after all? A missionary from China gave us a glimpse of what a nation is without Christianity, by remarking that, if a comrade were drowning, very frequently the natives refuse to go to his rescue; and a poor fellow actually drowned because the missionary could not make some fishermen move quick enough to go to his aid. They refused to stir until he would give them a sum of money something like five dollars. When he told them at once that he would give it, they insisted on having the money *first*. By the time the money was handed over, the poor man was drowned. I saw a newspaper statement in regard to the recent flood in Mississippi, in our own United States of America, where the colored folks refused to stir a peg to the relief of other colored people until they had been *paid for* laboring for the rescue of their own people; and, furthermore, they insisted on having their pay *before* they went to work. I am greatly surprised at this, for I had formed a pretty favorable opinion of our colored population in the South—at least of the intelligent and educated ones. I hope it is a mistake, and not true; or, if true, that there were only a few, comparatively, who took this stand. Had it been their own relatives and children, very likely these people would have stirred themselves at once; but as it was somebody else they didn't care particularly. Now, the man who is simply trying to lay up something for a rainy day, or against old age, sickness, and the like, is a good deal after this fashion; and if he steps no further, or goes no higher in his plan of lifework, he may both *lie* and *steal* in order to get the wherewith for a rainy day or for old age. Years ago, when we had saloons here in Medina, I went to a neighbor and remonstrated because he proposed opening a bar in his hotel. He said that he *must* do something to earn the wherewith to support his family and educate his children; therefore he opened the bar. *Before* the children were educated, however, he filled a drunkard's grave, and they had to educate themselves. Müller says, "If our possessing the necessaries of life depended upon our working, we could never have freedom from anxiety." There we have it. A man who is trusting to his own powers of mind and body—one who is trusting in the probability that he *may* have health, etc., has *great need* to be anxious, for all these things are but luck and chance; but, on the contrary, when he is trusting on the strong arm of the Lord, and has faith in him instead of in poor feeble human brain and muscle, then may he be at peace, for "*the Lord will provide*." Then, again, there is something wonderfully comforting in the little text I have chosen. I got it from Müller's book—"Ye are not your own, for ye are bought with a price." Oh I am so glad that I am *not* my own! It fairly makes my heart thrill to feel that Christ Jesus cared so much for *me* that he really wanted me to such an extent that he of his own free will and choice *bought* me with a price. Therefore I am his. He owns me, and I am not my own. I remember the dreary years of my earlier life when I called myself *my own*. I had become so old that I was no longer under my mother's charge, and my good father had decided to let me plan for myself. For a time I thought it was very nice to be my own boss and master. It was stepping out into pretty broad liberty when I felt myself no longer accountable to any one. I did not think of God—in fact, I thought *I* was *all-sufficient*. How soon I learned my mistake! Have you not learned it too, dear brother and sister? Oh! I do hope you have reached the point where you felt as I expressed it last issue—"*I* am *weak;* but *thou* art *mighty*." Again, the man who is not working or thinking about laying up something for old age or a rainy day, or for the children, has something to spare for *missionary* work. Müller says, in his quaint way, page 14 of the little book:

> I do not find in the whole New Testament one single passage in which, either directly or indirectly, exhortations are given to provide against deadness in business, bad debts, and sickness, by laying up money.

What a thought! An appeal may come for the suffering people in the South, or even from across the ocean, and you may say to yourself, "Well, I should like to give something with the rest of you. But suppose I should get sick, or should have losses in business, then what a sad thing it would be if I had sent the money away that I needed myself!" I wonder if there is a professing Christian whose eye meets this who has been guilty of such reasoning. Müller gives a great list of texts in this direction. Here are a couple of them:

> "There is that scattereth and yet increaseth; and there is that withholdeth more than is meet, but it tendeth to poverty. The liberal soul shall be made fat; and he that watereth shall be watered also himself" (Prov. 11:24, 25). In connection with 1 Cor. 16:2, I would also direct my brethren in the Lord to the promise made in Luke 6:30, "Give, and it shall be given unto you; good measure, pressed down, and shaken together, and running over, shall men give into your bosom. For with the same measure that ye mete withal it shall be measured to you again."

And now, dear friends, I am coming to a thought that has been on my mind for a long time—in fact, something has been said in regard to it in these pages already. It is, the starving brothers and sisters in Russia. Our church is to make a contribution next Sunday. I have been urging a long while; and when they decided to wait until next Sunday, I made the remark that ever so many hundreds and may be thousands might starve before our contributions get there. Of course, it is not as bad as the men who demanded five dollars in advance before they would stop fishing long enough to save a man from drowning; but I do think we should *make haste* to let it be known that our work, and our aspirations and plans here in this world of ours, go a little outside of family relations and family ties. Perhaps we can not, all of us, climb to the spiritual level where Müller stands, and *stay* there. I add the last, because one of my great weaknesses is to slip down so quickly, almost immediately after I have been lifted up. Here are some extracts that I made from two of our agricultural papers in regard to what has been done, and the needs in regard to the work. The first comes from the *Country Gentleman* of March 31:

> An appeal for prompt and liberal assistance is issued by the Russian Famine Relief Committee (John W. Hoyt, Chairman, 732 Fourteenth St., Washington), and deserves immediate attention. Every newspaper is asked to urge upon the attention of its readers the facts
>
> That the famine, so vast and dire, is not alone, but is supplemented by the freezing cold of a terrible winter, and by the distresses which come in the train of attending pestilence which may, if not soon checked, sweep over many other lands as well.
>
> That the famine is there to stay, even until after the coming harvest, unless banished by the benefactions of those in other and more favored lands.
>
> That the Russian government is exerting itself heroically for the rescue of the people, both by a munificence worthy of a great nation and by the sacrifices of those who administer the public affairs.
>
> That the extent of the famine is so great, and the revenues of the government have been so far crippled by repeated and widespread failures of the crops, that there is need of help from other friendly countries—help immediate, liberal, and persistent
>
> That, the rest of Europe having also been impoverished, the bulk of supplies must come from America, so wonderfully blessed with bountiful crops the past season that she can send shipload after shipload of food without perceptible drain upon her inexhaustible stores.

And here is what the *Rural New-Yorker* of April 20 has to say:

> Philadelphia was the first to send a shipload of flour to the relief of the starving Russians, and the steamer Indiana's cargo was received at Libau with public rejoicings and hearty thanks. The Minneapolis millers sent the next cargo through New York, and this is still at sea. The Philadelphians have almost completed another shipload, and the Western millers will send another also in a few weeks. Millers, farmers, and others all over the country are generously joining in the good work, and probably a dozen or more cargoes in all will be donated. Of course, this will be a Godsend to a comparatively few, but would hardly be a mouthful among the millions in distress.

HIGH-PRESSURE GARDENING.

BY A. I. ROOT.

EVERITT'S MAN-WEIGHT CULTIVATOR AND BREED'S WEEDER.

What do you think of Everitt's Man-weight cultivator and seed-drill? Is it not bad for the man's breast? Can you recommend it for rather stiff clay loam? Do you like Breed's weeder?

Alexandria, Va. A. JAMIESON.

[My good friend, the great trouble with both of these implements is, that the average gardener does not very often have the land or the kind of soil suitable for such machines; and another thing, the ground must not be too wet nor too dry. What I mean by "too dry" is, that if the cultivation has been neglected at the right time until the soil becomes baked, neither of these machines will be practicable; at the same time, by the *use* of these machines we ought to be able to *keep* our ground soft and mellow, unless we have too much rain. Underdraining the ground thoroughly is a great help; in fact, it is really a necessity. Ridging the ground up in winter time to let the frost work at it is another great help; and we have been so much annoyed this spring by having our ground too wet to work that I have begun to think seriously of plowing it in the fall when it is in proper trim, then throwing it up in ridges and planting our early stuff in the tops of the ridges, leveling them down slightly with some of these tools. One of the best crops of potatoes that I ever raised was worked entirely with a Breed's weeder. It was never touched with a hoe at all. But this was on our best creek-bottom ground that is slightly loamy. But this same piece of ground this spring has been too wet to work for a whole month. Everitt's cultivator is too poorly made to stand wear and tear; at least, the one he sent us pulled to pieces so much that we have become disgusted with it. I think he ought to furnish us (and, in fact, everybody else who has one of his poorly made machines) a new one free of charge. He evidently, however, does not think so, for I have written him about it, and he simply said they made them better now, without any offer to make good our loss. *Later.*—He has, since the above was in type, offered to send new parts.]

THE TROUBLE WITH RASPBERRIES; ALSO SOMETHING ABOUT SQUASH-BUGS.

A. I. Root complained that raspberries do not thrive as they used to. I wish that he would see whether the trouble is not from fungus or the root-borer, and report in the garden department. The injury is a serious one with us. I should also be pleased if Mr. Root would experiment with a hot-water spray for squash-bugs, and perhaps other insects. It has proved useful in some cases. L. WILLIAMS.

Delavan, Wis., April 7.

[I am inclined to think you are partly right, my friend. Examination shows a deadness of the roots, although I do not see any traces of the borer. Our new plantation, put out last spring, made a very poor growth during the fore part of the season; but in the fall the vines did pretty fairly, and seem to promise now to grow with vigor. In regard to the hot-water spray for squash-bugs, even if it succeeded perfectly it would be too much labor. With us they frequently come in droves within an hour; and in just a few hours the vines are destroyed or very much injured; so you see it would take constant watching. With the wire-screen bug-protectors, however, when they are once covered up, all trouble is at an end for, perhaps, a couple of weeks. I am inclined to think now that plenty of tobacco dust will also do the business; but instead of a little sprinkling, it wants a whole shovelful; and as the shovelful is worth all it costs, for manure, in localities where this dust can be had at a low price it will probably be the cheapest remedy for our insect-enemies on vines. The strong odor of the tobacco remains for a long while, even after the vines are so large as to crowd against the wire-cloth covers.]

THE AMERICAN PEARL ONION.

You say the Pearl onion has wintered again with you. It did not with me. I got a quart of you and planted them Sept. 15th, so that they made a good growth; but there are not more than a dozen left, and they were mulched with hay. Potato onions, planted the same day, about half wintered; planted Oct. 15th, one month later, all wintered. I shall try again, but plant so that they won't grow any in the fall. Irish potatoes winter all right in the ground here, not over two or three inches deep, and we had hard freezes for this country—4° above zero. You are right about the Hall treatment. It is the worst fraud of the age—not but that it is good, but it claims too much. Bees wintered all right, but I hear of some starving on account of no fall honey.

Grand View, Tenn., April 18. A. F. AMES.

[Friend A., I wish you had tried a part of your American Pearl onions without any mulching. They are very apt to rot, and I have sometimes thought the mulching helped to keep the ground damp, and thus make them rot. I am surprised to know that the potato onions, planted a month later, all wintered. This indicates that there is something about onions that we do not know all about.]

TWO MORE BAD REPORTS FROM THE AMERICAN PEARL ONION.

Extra Early Pearl onion will not live over the winter here. I got a quart of you last fall. They are all dead, rotten. M. ISBELL.

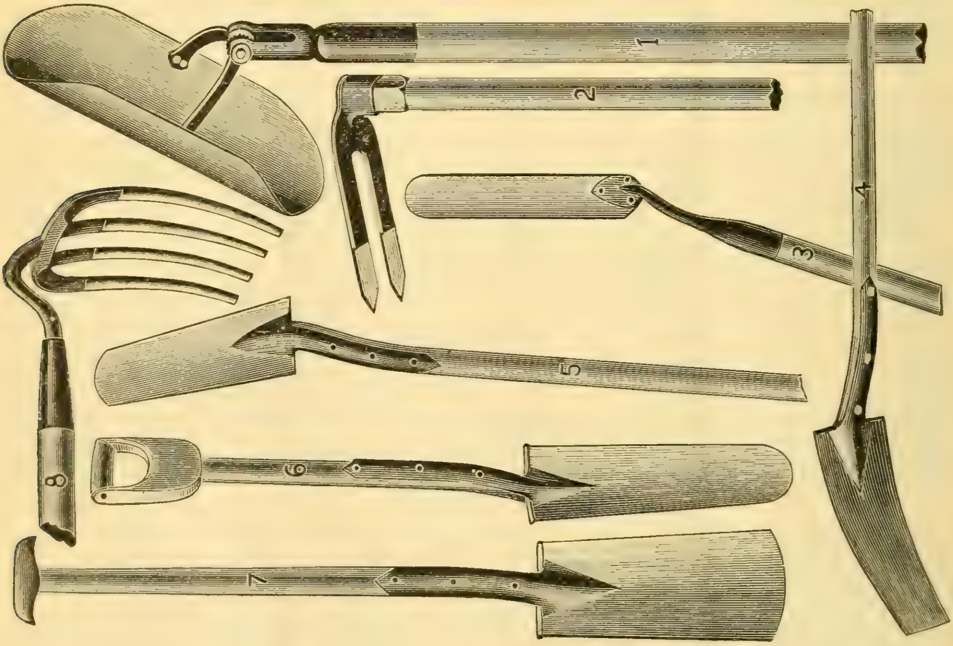
Norwich, N. Y., April 4.

There seems to be something wrong with the American Pearl onions that I got from you last fall. A third of them have from two to five in a bunch, like the multiplier onions. A half of them are running to seed. Is this the habit of this onion? A. T. MCILWAIN.

Abbeville, S. C., Apr. 4.

SOME TOOLS FOR THE MARKET-GARDENER.

The cut below is taken from our new book on tile drainage. It is a list of the tools selected by Prof. Chamberlain. As they are, however, very useful for many purposes besides ditching, I have thought best to speak of them a little here.



No. 1 is for grading and cleaning out the trench just before the tiles are laid. The tool is an exceedingly handy one; but I should prefer it with a permanent solid joint instead of the adjustable one as shown. In fact, I have taken quite a dislike to adjustable tools, or tools made for a great variety of purposes. One reason why I dislike them is, that the man who uses them will be fussing with the tool a good many times when I would rather he would be doing his work. If you are doing very much ditching it will pay to have two or more sizes of these bottoming-scoops to suit the size of tile.

No. 2 is what we call a "Dutch hoe." One of our men who recently came from Germany brought it along one day to pull the dirt into the ditches. The rest laughed at him; but pretty soon the hoe became a favorite tool with many of the men. It is good for grubbing and digging around trees, for digging roots, and, in some kinds of ground, it will work it up about as well as any thing.

No. 3 is for much the same purpose as No. 1; and it is exceedingly handy for many purposes.

No. 4 is a light, thin, narrow spade; but for myself I should prefer No. 5. Now we come to the regular ditching-spades.

No. 6 is for cutting the last course of the ditch. If the ditch is started with an even grade on top, and both Nos. 6 and 7 are pushed *clear down*, to a uniform depth, very little work will be required in fitting the bottom for the tile; for you notice the round end of No. 6 leaves it just about as you want it;* and, by the way, the bottom of the ditch should be very little wider than the bottom of the spade No. 6. It is on this point that I have a good deal of quarreling, especially with new men. They will dig the ditch twice the width of the spade, and have the bottom in such awkward shape that the tiles can not be laid true and regular. The excuse is, that they can not work in so narrow a ditch. Where a man won't do as you wish to have him do, or as he sees others do, I would turn him off and hire somebody who would. May be you think this does not sound like some of my teachings; but I mean, of course, that you are to use mild measures *first.* If that plan does not answer, then state the case kindly but firmly. And, by the way, No. 6 is a most valuable tool to have in the market-garden or on the farm. We have three of them—two with long handles and one with a short handle; and these ditching-spades are almost always wanted for a variety of purposes. If you want to take up trees they are far ahead of a common spade; for where the tool is a good one it can be used almost like a crowbar. For digging horseradish, or digging rhubarb roots for sale, taking up Egyptian onions, parsnips, carrots, vegetable oysters, and the like, they are the best thing in the world. The point is so narrow you can dig a dock out of your strawberry-bed and not injure very much besides the dock. If you have not had one on your premises, just let the boys get hold of one and see how they will learn to "go for" it.

---

*The following is from page 88 of our new book, Tile Drainage:

If the entire ditch is to be 30 inches, I usually try to make fully 7 or 8 with the plow, and 13 or 14 with the first spade, and that leaves only 8 or 9 inches for the second, or bottoming-spade. The subsoil at the bottom is far more compact and hard, and it is better not to have too deep a course to dig. Great care should be taken to keep the grade of this course exactly right, so that, when you draw the double-ended crumb-cleaner No.1, and groove-cutter through the few loose crumbs of clay that are always left by the spade of even an expert, you will leave a true groove ready for the tiles.

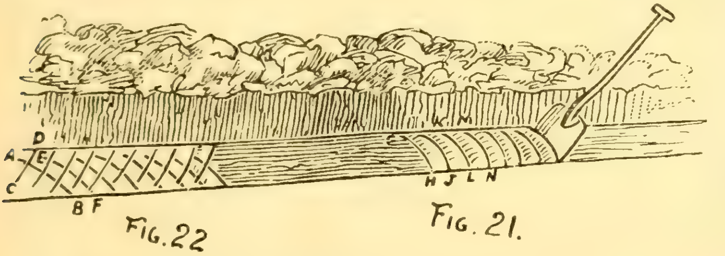


FIG. 22 FIG. 21.

HOW TO DIG, EVEN IN HARD CLAY, AND DO IT EASILY.

No. 7 is a tool that I never owned until I saw it recommended in the tile-book. When you are ditching through rich ground, take off the rich black surface soil with a common spade. Clean out the ditch down to the yellow dirt. Throw this good dirt to one side, and the rest of the soil (the poor clay) on the other side. Now take No. 7 and push it down full depth. Unless you have learned how, you will say you can't do it—the ground is too hard. I think, my friend, I can push both the spades, Nos. 6 and 7, down full depth on the hardest ground you have. If the ground is full of stones I can still do it and get out the stones quicker than you can do it with a pick or grubbing-hoe, and I will have a straight narrow ditch all ready for tiles quicker than a big stout man who works in the old-fashioned way. The secret of being able to do this is shown by the cut, and I copy here from the tile-book itself:

DON'T BURY THE SPADE.

The first point in rapid, easy digging, is to keep one side-edge of the spade *out of the earth, in sight,* each spadeful. Fig. 21 shows how a non-expert will bury both edges of the spade at *gh, ij, kl, mn,* and have harder work thereby, both in sinking the spade and in breaking off the slice of earth. Fig. 22 shows how an expert will sink his spade; *ab, cd, ef,* being the curves cut by the spade, and the edge *a* being "out" the first cut, and the edge *c* being out the second cut, and so on. Thus held, the spade sinks more easily, and the *one* edge breaks off true and easily.

SINKING THE SPADE.

This is done by a succession of quick "shoves" or thrusts with the foot, throwing one's whole weight upon the spade with a quick impulse, and working the handle slightly back and forth in sympathy with the efforts of the foot. It will take from two or three to six or eight "shoves" to send a sixteen-inch spade "home," the number varying with the hardness or stoniness of the clay and the skill and muscle of the digger. The best way to get this motion is to watch a real expert and get him to teach you. I almost never use a pick or mattock. A good ditching-spade well handled will dig almost anything but the stoniest clayey gravel faster alone than with the help (?) of the pick, by working *around* the stones.

No. 8 is to be used much like No. 2. The tool we use, however, has flat tines instead of round ones, as shown in the cut. The tines are flat on the inside and rounded on the outside. It is called the filling-hook; but it is useful in a great variety of places on the farm or in the garden. It will pull straw out of a stack, pull manure on to a stoneboat, level down hummocks in the field, dig potatoes on an emergency, and do a variety of such work. With a set of tools like these, many kinds of work as well as underdraining may be done; and a man who is expert in the use of tools will oftentimes do *double* the work by having *just the tool* he requires.

We presume that you can find these tools at your nearest hardware store; and, in fact, it is usually the best way to get them, on account of the expense of shipping such bulky articles. If, however, you prefer to get them of us, we can furnish them as follows: No. 1, $1.25; Nos. 2, 3, 4, 5, 6, 75 cts. each; and No. 8, 50 cts. No. 7, $1.25. A single tool is rather expensive to send by express; and it is also rather expensive and inconvenient to send by freight unless it goes along with other goods. If, however, you should want several tools they can be made into a bundle so as to go by freight at moderate expense. In case you do not buy of us, the figures above may indicate to you about what prices you *ought* to pay.

TRANSPLANTING FROM GREENHOUSES OR COLD-FRAMES INTO THE FIELD.

There is one thing in friend Day's tomato-book that pleased me greatly. It was, a recognition of the fact that there is a tremendous gain in moving plants to the field with dirt adhering to their roots; and he even moves his tomato-plants in this way, for planting out acre after acre. I have for years been satisfied of the importance of this, but yet the whole great wide world, almost, seems stupid in regard to the matter. They say it is too much fuss, and takes up too much time, and so they let the dirt rattle off, sometimes taking the fine roots with it, and lose half of their crop, then quit the business, etc. To-day we are moving celery-plants from the greenhouse to the field. After the plants are thoroughly wetted down in the bed, a scoop-shovel is pushed under a sod of plants. These scoop-shovels are carried to the field in a wheelbarrow. Each man has one; and as he sets the plants he picks them from the shovel with a ball of rich earth adhering to the root, and places it in the furrow. Of course, the plants will live—every one of them—and grow outdoors just as they grew in the greenhouse. If you haven't scoop-shovels enough, gather up your barn-shovels, potato-forks, etc., and use those.

TOBACCO COLUMN.

Before giving the following brief extract from a letter just received, we wish to say that GLEANINGS does not propose to open its columns to discuss politics. I am sure it would not be wise nor well. But where two political parties are alluded to in the following, we wish it understood that their names are mentioned solely because of their bearing on the question of the use of tobacco. If our good brother's statements are not true, we may give place to something very brief, showing wherein they are not true. You will notice that he and I evidently do not quite agree in politics. I am glad, however, that we agree perfectly on the tobacco question. Here is the extract:

I do not know how much you have associated with Prohibitionists—whether you ever attended any of their conventions, or have read *their* side of the question or not; but I will tell you just what kind of a "crowd" they have. I never saw a delegate smoking a cigar. Neither did I ever hear a profane word used by one of the delegates. Neither did I ever see a stub of a cigar, nor a chew of tobacco, nor a particle of tobacco-spit on the floor when they had finished, and I should have seen it if there had been any. I have seen in our own county courthouse, before the Republican County Convention adjourned, a new carpet completely saturated with tobacco-juice, with quids of tobacco and stubs of cigars covering it, while the room was blue with cigar-smoke. VOLNEY WHITE.
Findley's Lake, N. Y., April 11.

Please send to George Bates a smoker. His address is Davis City, Iowa. He has quit using tobacco, and I think he is safe. If he ever uses it again I will pay for the smoker. He is raising a family of boys, and his influence on them will be better. A. S. ROSS.
Decatur, Ia., Feb. 25.

Mr. Andrew Hudspeth has, through reading GLEANINGS, discarded the use of tobacco, and says he has quit for good. If you feel so inclined you can send him a smoker; if he ever begins the vile habit again I will pay you for the smoker if sent. M. F. RAGSDALE.
Collinsville, Texas.

I think I may lay claim to one of your smokers that you offer to all readers of GLEANINGS who quit the tobacco habit. This I have resolved to do. I have not used any for two and a half months, and do not intend to again. If I do, I will pay for the smoker. I have been a user for about 22 years. J. M. CAMPBELL.
Glidden, Ia., Feb. 16.

Mr. Lafayette DeWitt, of Sunny Side, Md., has stopped the use of tobacco, and he agrees to pay you 75 cts. for it if you will send him a smoker and if he uses tobacco again. Also Mr. F. B. DeWitt has stopped the use of tobacco, and he agrees to pay you for the smoker if he ever uses tobacco again. His address is Sunny Side, Md. M. H. DEWITT.
Sunny Side, Md., Jan. 4.

According to the terms of the Tobacco Column I believe that I am entitled to a smoker. I have been using tobacco for upward of thirty years, and through the influence of some friends and GLEANINGS I have given up the filthy habit. So if you will send me a smoker I will agree to pay for the same, if I ever use the weed again in any form. FREDERICK MULSON.
Baldwin, Kan., Feb. 10.

GLEANINGS IN BEE CULTURE
A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS
ILLUSTRATED SEMI-MONTHLY
36 PAGES 7×10
$1.00 PER YEAR

If ye then, being evil, know how to give good gifts unto your children, how much more shall your heavenly Father give the Holy Spirit to them that ask him?—LUKE 11:13.

ALL photographs designed for half-tone reproduction should be made with a *light* background; and especially is this true for portrait work. Half-tone work, while so beautiful, and admired by many, has a tendency to obliterate lines, and therefore the contrast between objects should be strong.

A GOOD many are now receiving consignments of hives in the flat. After they are unpacked there is a liability that some of the boards will warp a little. Do not try to spring them into shape by nailing the hives or by putting cleats on the covers. First wet the concave side of the boards and lay them on the floor, wet side down. In a few hours they will be straight, and then they can be nailed together.

WE desire to call special attention to Prof. Cook's able article on page 322 of the present issue. It is one that should be copied widely; and bee-keepers should take pains to see that their fruit neighbors are properly informed; for we feel very sure that no fruit-man wants to do any thing that will work damage to his bee-keeping neighbor. All he needs is the knowledge of *when* and *how* to spray, in order to kill codling-moths and yet not destroy bees.

THE Leahy Manufacturing Co., of Higginsville, Mo., seems to be booming things. GLEANINGS wishes them success, even if they enter into competition in the supply business. We have a good big country, and there is plenty of room for all; and although we employ every legitimate means to stimulate trade, we do not want the "whole loaf," and therefore welcome new business enterprises in the bee-keepers' supply line.

ALMOST every mail brings a letter offering either to sell bees to us outright or to give them in exchange for goods. We are obliged to say to one and all that it is not profitable for us to buy bees from a distance, as the express would cost more than they are worth. Another thing, the bees are not in such frames, nor such stock, as a rule, as we care to send out again to our customers. If you wish to reduce your stock of bees, the better way is to offer them for sale in your local paper first; i. e., sell 'em around home. If that does not dispose of them, try the bee-journals.

As we have said several times before, we repeat again: If you differ from the position taken by the editor—that is, if you are sure he is wrong, and that, if such position is not corrected, it will work damage to the industry, be free to correct him; but for goodness' sake, do it in a gentlemanly and courteous manner. We have not time to bother with unkind flings. Time is too precious to waste in following up and answering such attacks; but we do desire to be on the right side; but if on the wrong side we are glad to be set right. Alack the day when we shall get into ruts and stick to wrong notions! Gleanings desires to be fair to all parties, and to all sides of a question; but it has no space for sarcastic and cutting witticisms.

Some years ago Mr. Langstroth wrote an article on nomenclature for bee-keepers. At the time, he suggested the coining of new words, the use of which was almost a necessity. He proposed, for instance, the term "unqueening" for the circumlocution of removing or in any way depriving a colony of their royal mistress. We believe that he also suggested the term "springing" for the long roundabout way of saying "bringing the bees through the spring months." It is a well-known fact, that it is not so difficult to *winter* bees as it is to *spring* them; and if it is proper to say "wintering," why not say "springing"? We simply mention these two words as an illustration, because we propose to allow — yes, recommend — correspondents to use such short and expressive terms, the meaning of which is perfectly evident to every bee-keeper.

One of the commission honey merchants says that they have much complaint of comb honey candying. This can be remedied to a very great extent by keeping the honey in a warm dry room; but, in spite of all precautions, old comb honey is liable to candy on our hands: and when once candied there is no practical way of reducing the honey to a liquid form again so as to be suitable for the market, or to bring any thing like what the honey is worth. And right here is one great advantage in extracted honey. It can always be liquefied, and, with care, be equal in flavor to what it was before. But, oh dear! extracted honey can be adulterated; and for this reason bee-keepers should take additional pains to fight to the bitter end the disreputable mixing business. Be sure to urge your representative to vote for the Paddock pure-food bill now before Congress; and after you have done that, don't let the adulteration go on if you can help it, in your neighboring city or neighboring town. There is plenty of law in nearly every State to make the scamps squirm; and all we need is evidence.

Do not put poor dark honey—that is, the unpalatable kind—upon your local markets, nor upon any markets, in fact, that are designed to supply direct consumption. It is putting this dark honey upon the public that ruins, in a great many cases, the demand for honey; and, as C. W. Dayton well says in the *Review*, it fans the fire that keeps up the newspaper "canards" in regard to adulterated honey. All such unpalatable honeys should either be fed back to the bees in the spring (in most cases it will do no harm, even if fed for winter use), or should be sold to bakers. If nothing but the well-flavored nice honeys are sold for direct consumption, it will tend greatly to increase the amount sold, and, as a consequence, stiffen prices. We would say, for the benefit of the York State bee-keepers, that these remarks do not apply to the dark rich buckwheat honey that is preferred by so many New Yorkers. We have reference only to the honey that tastes bad —"stuff" that bee-keepers would not eat themselves—no, couldn't even be hired to. To put it a little stronger, it is a downright shame to put such "stuff" on the market and call it honey. The sooner bee-keepers will give up the practice, the better it will be for the pursuit in general.

SEALED COVERS VERSUS POROUS ABSORBENTS FOR WINTERING.

Elsewhere we publish several communications in favor of upward ventilation and porous covering as against the sealed-cover idea. As nearly as we can discover, both from the letters published and those unpublished, the writers have not tried both the sealed cover and the absorbing cushions side by side for a series of three or four years. All through the *winter* we could discover no practical difference in our apiary; but this *spring* there is a slight difference in favor of the sealed-cover colonies. Those under sheets of glass seem to be stronger and more lively than those under the absorbing cushions, and they are the first to fly out. At present, however, we are seeking for more light, and at present are not prepared to advocate either method as being the best. It may take three or four years of careful experimenting on the part of a good many to decide the question. Francis Danzenbaker, of Washington, D. C., in another column, the inventor of the Dual hive, and the one who suggested to us the adopting of the dovetailed corner for the Dovetailed hive, you will notice says he has tried the sealed covers for twenty years, and that he has also tried the porous covering, with disastrous results. Now, who is there, besides the Dadants, who have tried the sealed covers and porous covering side by side, and found the latter as good as the former?

MORE ABOUT IMBEDDING WIRES INTO FOUNDATION BY MEANS OF ELECTRICITY.

Some two months ago a correspondent of the *American Bee Journal* stated that he had succeeded in imbedding wires into foundation by means of electricity from a battery. This set us to thinking and experimenting, although we had entertained the same ideas some eight or ten years previously; but on account of the intersecting wires by the old way of wiring, the plan was not feasible. But since we are beginning to use the horizontal plan, no wires intersecting, so that a current can be run from one end of the wire to the other, the matter has assumed a new aspect. In our last issue we stated the progress of our experiments. Since that time we have been imbedding the wires to a lot of frames by electricity. The form of battery that we now employ is three cells of bichromate of potash, each of a gallon capacity, with the carbons in the large cell, and the zinc in the usual porous cup. Since Mr. Golden's article appeared in type, as given in another column, we began experimenting anew; and the result is, that we find we can imbed the foundation on the wires perfectly. After the job is done, the wire lies nicely imbedded in the center of the wax; and, more than all, it is covered with a very thin transparent coating of wax. Sometimes bees are inclined to gnaw around the wires; but we imagine that, if the wires were covered with a film of wax, the bees would be less inclined to do so. However, experiment will decide this point. At present it looks as if imbedding by means of electricity might not be so very expensive after all, and especially so if we consider the nicety of the work. We imbedded this morning the wires of about 50 frames into foundation by electricity, and the work is beautiful. By timing ourselves we found that we could put foundation on to wires at the rate of three frames per minute; so that we think the imbedding could easily be done at the rate of 150 frames per hour. In our next we will try to give you a picture of the apparatus, and how to make it.

We ought to say right here that it probably would not pay the small bee-keeper to imbed his wires by electricity; but it looks now as if it would be quite a saving in time for the large bee-keepers and all supply-dealers.

PRODUCER AND CONSUMER—MAKING A SHORT CUT FROM ONE TO THE OTHER.

While we sat at the foot of Wilson's Peak drinking our lemonade, friend Stevenson suggested that evaporated fruits were, in many parts of California, a drug. He said he had some beautiful apricots of his own growing and evaporating that he would be glad to sell at 7 cts. per lb. I told him to send me a barrel. They reached us safely at a cost of 2 cts. per lb. for freight. He paid the freight in advance, so as to be sure there would be no overcharges. Well, they proved to be about the finest fruit that our Medina people had ever got hold of. The boys put them on the wagon, and they sold nearly half the barrel the first trip they made through the town. We retailed them at 12 cts. per lb., and this is about what they are worth at wholesale in Cleveland. Now, the point is, by this operation we made a short cut, like cancellation in arithmetic, skipping the middlemen, as has been talked of. Of course, you know I do not mean to intimate that "middlemen" are not good members of society; but they are not *always* needed. When we can make a short cut crosslots, to the benefit of both parties, by all means let us do so. The question then is, How shall we find out who has nice stuff for sale? and who else it is that wants it. Why, I think our home journals should be the medium of this sort of exchanges—a brief notice in the "Wants" and "For Sale" column, for instance. The next point is, that both buyer and seller should be good square men. I do not know whether friend Stevenson has any more left or not. If he has not, I think very likely his neighbors have. His address is, Wm. Stevenson, 80 Orange Grove Avenue, Pasedena, Cal. A. I. R.

POLISHED

One-Piece Sections Our Specialty.

I challenge comparison of my goods with those of any other make on the market. If, upon fair trial, they are not found superior to, and cheaper than, any makes of so-called snow-white, premium, sandpapered, etc., sections, the goods will cost you nothing, and you are invited to publish me as a fraud.

I can fill orders promptly for any width at $2.75 per M.; or $2.50 per M. in 5000 lots at factory at Wauzeka, Wis. Other supplies shipped from Capac.

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All advertisements intended for this department must not exceed five lines, and you must SAY you want your adv't in this department, or we will not be responsible for errors. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. This department is intended only for bona-fide exchanges. Exchanges for cash or for price lists, or notices offering articles for sale, can not be inserted under this head. For such our regular rates of 20 cts. a line will be charged, and they will be put with the regular advertisements. We can not be responsible for dissatisfaction arising from these "swaps."

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they wish to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough in these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I have, by purchase and otherwise, 30 hybrid and mismated queens at 20c each; or 4 for $1.00. Can ship by return mail. W. H. Laws, Lavaca, Ark.

I have 50 good hybrids and black queens for sale at 25c each, ready for immediate delivery.
6-7d W. H. Heastman, Citra, Marion Co., Florida.

To all who will send me cages filled with candy, and stamp on, you take risk of loss, I will put hybrid queens 25c. C. C. Kirkman,
Redallia, Pitt Co., N. C.

30 black queens, 6 hybrid, to mail May 10 to 15. Blacks, 25c; hybrids, 50. Safe arrival guaranteed. None but good queens sent, stamps taken.
E. F. Quigley, Unionville, Putnam Co., Mo.

Twenty-five to thirty mixed queens, some pure and purely mated. Choice in turn. Price 25c each. Ready May 1 to 15. Dr. J. W. Crenshaw,
Versailles, Woodford Co., Ky.

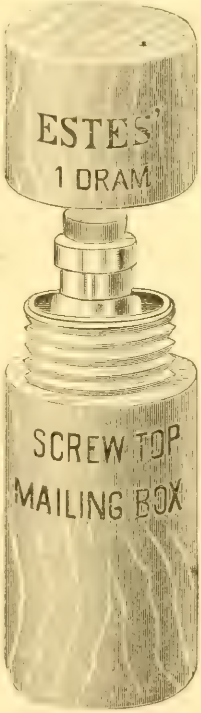
MAILING . .
. . BLOCKS
—FOR—
SAMPLES .
—OF—
. . HONEY.



The adjoining cut shows a very convenient package for mailing samples of honey and other liquids. The cut is only about half size of the one we are prepared to furnish, which holds ½ ounce, and gives a good taste of the honey and some to spare. We also use a very wide-mouthed bottle so the honey will run out easily. You notice the top screws on, closing it tight and making a very handy package, easily opened, and accepted by the postal authorities. We have just bought 25 gross so as to be able to sell them at only 5c each, 55c per doz. By mail, 3c extra on one, or 2c each extra in quantities.

A. I. ROOT,
Medina, O.

KIND WORDS FROM OUR CUSTOMERS.

I think GLEANINGS is an excellent paper. I don't see how I can ever do without it. A. J. BUCHER.
Decherd, Tenn., Apr. 11.

How far does GLEANINGS go? I still have orders rolling in for carnations which I advertised. I shall not be surprised to get an order now from Japan or some other far country, telling me that they saw it in GLEANINGS. S. LENTON.
Piru City, Cal., April 4.

I have got to be with you in your religious talks, and I think Our Homes was the thing that set me to thinking, and finding Christ, more than any thing else. GEO. ALLEN.
Union Springs, N. Y.

I should be lost, almost, without GLEANINGS' regular visits; and long may it live and prosper is my wish. E. D. NICHOLS.
Montrose, Colorado.

I have just received a nice lot of your new Hoffman frames, and think they are the finest I ever saw. I shall use them altogether this season.
Mocksville, N. C. E. E. HUNT.

OUR BOOK ON TILE DRAINAGE.

A. I. Root, of Medina, O., has recently brought out another of those excellent little handbooks for farmers. This is one on tile drainage, and is by W. I. Chamberlain, late president of the Iowa Agricultural College. Mr. Chamberlain dug this book out with the spade. In other words, it is his own experience, and we shall have more to say of it after awhile.—*Western Stockman and Cultivator, Omaha, Neb.*

Job Lot of Wire Netting.

CUT PIECES AT A LOWER PRICE THAN FULL ROLLS.

Having bought from the factory, at our own price, five or six hundred remnants, as listed below, we are able to give you the choice of a great variety of pieces at the price of a full roll or lower. Full rolls of netting are 150 ft. long, and when they are cut we have to charge nearly double the full-roll rate, because it is so much trouble to unroll, measure, and cut, and run the risk of having a lot of remnants on hand. No doubt it is in this way that the following remnants have accumulated. It costs a good deal to get all this in shape so we can easily pick out from the lot the piece you want. But to move it off quickly, we put the price down so you can all have a chance at it. Remember, first come, first served. In ordering, therefore, name a second or third choice, or say that we may send the nearest we can if the piece selected is gone. On 5 pieces deduct 5 per cent, on 10 pieces 10 per cent. These remnants are shipped only from here. If any of you want to secure some, and don't want them shipped till later, when you will order something else, so as to save freight, pick out the pieces you want, send remittance with the order, with request to lay by till called for, and we will mark them as belonging to you. We prefer to ship them right out, however.

LIST OF POULTRY-NETTING REMNANTS.

Width in in's.	Size of Mesh.	No. of Wire.	Cts. p'r Sq. Ft.	Length of each piece. Multiply by the width in feet to get the number of square feet in each piece. Then multiply by the price per foot for the price per piece.

"	"	Mulberry,	7	8
"	"	Lombardy Poplar,	6	2
"	"	Castor Bean,	8	4
Jas. Hogg,	Seven Rivers, N. M.,	Peach,	7	2
"	"	Cottonwood,	16	3
R. M. Gilbert,	Seven Rivers, N. M.,	Osage Orange,	14	7
"	"	Native Willow,	16	5
"	"	Pecan,	6	2
"	"	Blackwalnut,	4	11
"	"	Plum,	8	1
"	"	Mulberry,	6	4

Witt Bros. have several cottonwoods, 9 years old, that are 62 to 64 inches in circumference and over 60 feet high. Mr. Hogg has a peach-tree 3 years old from the seed that is 3½ inches in diameter and 17 feet 5 inches high. He has a cottonwood 4 years old that is 28 inches in circumference. Mr. Gilbert has a pecan-tree 6 years old that is 24 inches in circumference and 22 feet high. He has a blackwalnut-tree 3 years old, from the seed, that is 12 inches in circumference, 11 feet 10 inches high, and that bore several walnuts this year. Maynard Sharpe, of Eddy, has 2 peach-trees, 2 years old, from the seed, that bore and matured 7 peaches this year. He has 1 apple-tree, 2 years, from the seed, that bore 3 apples the past season.

Apples, Peaches, Pears, Apricots, Nectarines, Figs, Prunes, Almonds; Muscat, Tokay, Muscatelle, and other varieties of Grapes now in successful bearing in this Valley. Over 1000 acres of Muscat Grapes being planted this year.

Send for maps, illustrated book, etc.

CONVENTION NOTICES.

The Capital Bee-keepers' Association will meet in the Supervisor's Room of the Court-house, Springfield, Ills., at 10 A. M., May 25, 1892. C. E. YOCUM, Sec , Sherman, Ill.

SPECIAL NOTICES.

CORRECTION.

Since the editorial on adulterated honey on page 387 went to press (see beginning of the next to the last paragraph) we have just received a letter from Chas. F. Muth, to the effect that he did not send samples of any honey to Prof. Wiley to be analyzed, and which, as stated elsewhere, were, by the professor pronounced adulterated. We were misinformed on this point, and therefore in justice to Prof. Wiley, make this correction. Our readers will therefore make a note of this.

LAWN-MOWERS.

Now is the time for trimming the lawns and bee-yards to make them neat and attractive. You can not do this successfully without a good lawn-mower. We are prepared to supply you with one of the best mowers on the market at prices lower than former years. We sell the Globe in five sizes, as follows: 10 in., $4.65; 12 in., $5.00; 14 in., $5.35; 16 in., $5.65; 18 in., $6.00. We have also the Young America, a single driver, in two sizes, as follows: 10 in., only $3.50; 12 in., $4.20. In lots of 2 at a time, 3 per cent off; 3 together, 5 per cent off; 5 or more in one order, 10 per cent off. The quantity may be made up of assorted sizes, and both kinds if desired.

OUR INDUSTRIAL BOOKS ON AGRICULTURE, ETC.

We have now in stock, ready to send out, five books, as follows: The A B C of Potato Culture; The Winter Care of Horses and Cattle; The A B C of Strawberry Culture; Tile Drainage; Maple Sugar and the Sugar-Bush. The regular price of the above would be $2.00. If ordered all at once, however, we will furnish them postpaid for only $1.50; if sent by freight or express with other goods, only $1.25. For only 25 cts. more we will include the book on tomato culture, as described below.

THE NEW BOOK ON TOMATO CULTURE.

Well, it has got started, and the title-page reads: "Tomato Culture; In three parts; Part First, Tomato Culture in the South; Part Second, Tomato Culture Especially for Canning-factories; Part Third, Plant-growing for Market, and High-pressure Gardening in General; A Practical Book for those who Work under either Glass or Cloth as Protection from Frost; by J. W. Day, D. Cummins, and A. I. Root." The first 32 pages are already printed; but if you are in a hurry to make use of the information it contains, send us the price of the book now and we will send the proof-sheets as fast as they come from the press, and a complete bound book as soon as it is finished. We make this offer because it usually takes several months to finish a book complete, make engravings, etc.; and at the same time the matter contained in one of these industrial books may save you many dollars, even in a single season. Part III., by A. I. Root, will contain a chapter headed, "How to Support a Family on a Quarter of an Acre of Ground." In order to be sure that I am right in my undertaking, I have visited, and expect to visit, all the prominent men I know of who make their living by raising crops under glass and under cloth; and this new matter of warming the ground by steam carried through common drain tile, so as to force crops without the aid of either *glass* or *cloth* is going to be very fully considered. The price of the book will be 35 cts.; by mail, postpaid, 40 cts. The engravings alone will cost over a hundred dollars.

SELLING ONION-PLANTS.

This is the exciting topic now with plant-growers. Pretty much every vegetable-plant grower has raised more or less of them, but no one has enough to supply the demand. The prevailing price seems to be $1.00 per 1000 as they come from the seed-bed; and where they are raised so as to have them, the greater part of them, the size of a common lead-pencil when set out, they go off like hot cakes; and there is money in raising the plants for sale, too, I tell you. At present we have a large stock of Prizetaker and White Victoria. They will be large enough to transplant in very few days, and we hope to have enough for all demand; but I tell you, people are going for them lively. The postage on a thousand plants depends somewhat on the size; but it generally runs from 25 to 50 cents.

PURE ITALIAN BEES.

By the pound, 90 cents. Untested queens from imported mother, 90 cts. Two-frame nuclei, both frames containing brood with all adhering bees, and untested queen from imported mother, $2.00. Tested queens, $1.50. Satisfaction guaranteed.

A B C OF STRAWBERRY ✢ CULTURE.

A ✱ BOOK ✱ FOR ✱ BEGINNERS.

BY T. B. TERRY.

This is Terry's latest and best work, and has received some very high words of praise. Who that keeps bees does not also have a little garden-patch? If you would learn to raise in it that most luscious of all fruit, the strawberry, with the best results, you can not be without this little book. Even if you don't grow strawberries you will be the better for reading it. Pages one-half size of this. Fully illustrated; 144 pages. Price 35c; by mail, 40c.
A. I. ROOT, MEDINA, O.

HONEY COLUMN.

CITY MARKETS.

NEW YORK.—*Honey.*—Very little demand for comb honey; season about over; quite a little of it on the market; that is, buckwheat and fair, but no fancy. Quite a little demand for extracted southern honey, with very little on the market; none coming in of any account. Prices range from 65@75c per gallon; demand for clover and buckwheat extracted on the decrease. Clover, 6½@7; buckwheat, 5@6. *Beeswax* keeps firm at 27@29.

May 10. CHAS. ISRAEL & BRO.,
110 Hudson St., New York.

KANSAS CITY.—*Honey.*—Demand poor, with supply well cleaned up. We quote: Comb, 1-lb., fancy, 12; dark, 8@9. Extracted, white, 7; dark, 5@6. *Beeswax*, none on the market.

May 9. HAMBLIN & BEARSS,
514 Walnut St., Kansas City, Mo.

ST. LOUIS. *Honey.*—New extracted is arriving; some few inquiries. Sales moderate. We quote: Extracted, 5@5½; cans, 6½@7. No demand for comb honey. *Beeswax*, 27½.

May 9. D. G. TUTT GRO. CO.,
St. Louis, Mo.

ALBANY.—*Honey.*—The continued cool weather and short maple-sugar season has favored the continued sale of comb honey, and we would have closed out all of our stock had we not received three or four small consignments during the past week. Prices continue unchanged, 5@10. Extracted, 6@8. *Beeswax*, 26@28.

CHAS. MCCULLOCH & CO.,
May 9. Albany, N. Y.

CHICAGO. — *Honey.* —Very little change since last quotations; comb is slow, but offerings are not large. Extracted is steady, and prices firm at 6@7@8, clover bringing the highest price. *Beeswax*, 27.

R. A. BURNETT,
May 7. 161 So. Water St., Chicago, Ill.

CINCINNATI.—*Honey.*—There is a general dullness prevailing in the demand for comb honey, with prices nominal at 12@14 for best white in a jobbing way. Demand for extracted honey was slow for the last few weeks, at 5@8 on arrival.

Beeswax. — Demand fair, at 25@27 for good to choice yellow on arrival.

May 9. CHAS. F. MUTH & SON,
Cincinnati, O.

BOSTON. — *Honey.* — No change in the honey-market. Slow sale, and fair stock on hand.

May 9. BLAKE & RIPLEY,
Boston, Mass.

DETROIT.—*Honey.*—No change in prices since last quotations, and not much honey left to quote. *Beeswax*, in fair demand, 27@28.

May 9. M. H. HUNT,
Bell Branch, Mich.

KANSAS CITY.—*Honey.*—The demand for comb honey does not increase very fast. Sales slow. No. 1 white comb 13@14c; No. 2, 12@13; No. 1 amber, 11@12; No. 2, 6@8. Extracted, white, 6@6½; amber, 6; dark, 5. *Beeswax*, 23@27.

CLEMONS, MASON & CO.,
May 10. Kansas City, Mo.

JUST OUT!

TILE ✠ DRAINAGE.

BY W. I. CHAMBERLAIN, A. M., LL. D.,

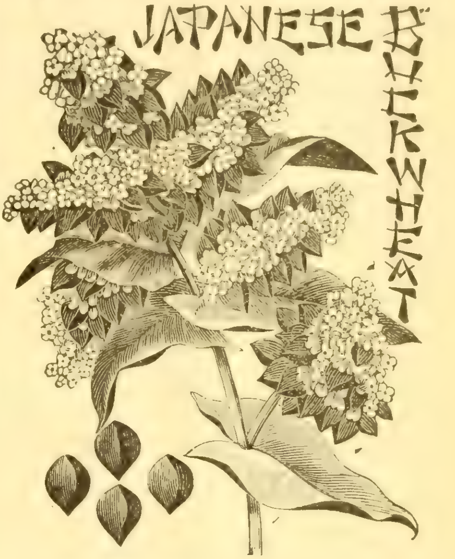
Formerly Secretary of the Ohio State Board of Agriculture, and late President of the Iowa State Agricultural College. At present Associate Editor of the Ohio Farmer.

This is a valuable companion to our other rural books. It embraces the experience of forty years of one of our foremost practical agriculturists, who has laid with his own hands over 15 miles of tile.

Price 35c; by mail, 40c.

A. I. ROOT, MEDINA, OHIO.

Japanese Buckwheat.



This is one of the most profitable of farm crops, and is especially valuable to the bee-keeper because of the pasturage it affords for the bees. It is harvested within three months from the time it is sown. Under fair treatment it yields 50 bushels to the acre, and rarely brings less than 50c per bushel. The time for seeding is at hand and we are prepared with several hundred bushels of choice seed, which we will sell as long as it lasts at the following prices. Former years we have run short and had to advance prices in June so as to supply orders without a loss. We hope to have enough this year for all orders, but we advise you not to put off ordering too long.

Per bushel, $1.00; ½ bushel, 60c; per peck, 35c; 1 lb., 5c. If wanted by mail, add 9c for postage. Two bushels for $1.90; 10 bushels or more, 90c per bushel. Above prices include bags to ship in.

A. I. ROOT, Medina, O.

"AND DON'T YOU FORGET IT"

I TELL you what, Jones, **Levering Bros.** sell the best goods and at the lowest price of any one I've struck yet. The largest and best equipped

GLEANINGS IN BEE CULTURE

A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS.

ILLUSTRATED SEMI-MONTHLY

PUBLISHED BY A. I. ROOT.

$1.00 PER YEAR MEDINA OHIO

Vol. XX. MAY 15, 1892. No. 10.

STRAY STRAWS

FROM DR. C. C. MILLER.

WHAT a spring!

THESE STRAWS average longer than usual. Wet weather always makes straw grow long.

EDITOR COWAN is making a tour in North Africa. Now he can procure pure Punics per private purchase right in the town of Punic, Punic province.

BINGHAM has made his smoker still better by giving it a crooked nozzle with a cool handle, so you needn't turn it upside down to use, nor burn your fingers filling it.

FRIEND NEWMAN thinks it is time to raise the question as to the best date for holding the convention at the World's Fair. Make a motion, T. G. How would the last of September do?

ANTS IN HIVES can be driven away, says the *B. B. J.*, by a liberal sprinkling of powdered naphthaline. The *Indiana Farmer* says a free use of common salt will produce the same result.

A STANDARD SECTION $4\frac{1}{4}$x$4\frac{1}{4}$x$1\frac{7}{8}$ has been adopted by the Utah Association. Good move. They also resolved, that, hereafter, "honey shall be sold by such standard instead of by weight."

ISN'T THERE just a little bit of confusion about speaking of absorbents as synonymous with upward ventilation? May there not be absorbents with tight covers as well as with upward ventilation?

GOLDEN PUNICS is what Alley says he's going to have before the season of 1892 is over. Next year I suppose he'll tackle the common blacks, put a few yellow stripes on them, and then we'll have Golden Blacks.

EDITOR NEWMAN is again at his post, "rested and invigorated." Like a sensible man, he has resolved to husband his strength and let some things go. If kindly wishes would strengthen him, he ought to be a pretty strong man.

I TOOK my bees out of the cellar April 7, and I think it was all right, as they were in bad condition from not having had fire in the cellar. But with fire through the winter, I think they would have been better off in the cellar till May 1.

WARPED BOARDS can be treated as advised on page 342, but I'll tell you a better way, if it's warm weather. Just lay them on the ground in the sun, hollow side down, without any wetting, and see if they don't come "straight as a board."

ALLEN PRINGLE (*C. B. J.*) thinks I ought to get a Webster. Got one, friend Pringle, but it doesn't make *available* mean "in readiness," or "get-at-able." I'm afraid such definitions are hardly available. Where did you get them, anyhow?

THIS SPRING I've used 45 of the old-fashioned Miller feeders, the bees going up at the sides, and 22 with the Warner improvement, the bees going up in the middle. To my surprise I don't find that the bees make any difference. It certainly seems they ought to.

FROM MEDINA I have a beautiful specimen of imbedding wire by electricity, and Fred T. Hayes sends me some thin surplus foundation perfectly wired by the same method. He says it is the outgrowth of Miss Wilson's heat method, which he used satisfactorily last year.

A NEW SYSTEM of working bees, by Mr. Wells, is making some stir in England. He puts two colonies side by side, with a perforated dummy between, and queen-excluder over, having both colonies work in the same supers, and reports great success. But it seems to increase the tendency to swarm.

ELECTRICITY takes the premium for imbedding wire in foundation. It makes a more regular job of it than Emma does with ordinary heat, and her plan is ahead of any previous imbedding. Just looks as if the wire grew there. Now, friend Root, if you can get up cheap batteries, may be the rest of us can use electricity.

I MOVED 28 colonies of bees about 10 rods, May 4. Shut them up before flying in the morning, moved them to their new location, and opened them at dark, putting a board in front of each hive. Set a hive with two empty combs in the old location, to catch returning bees. Got less than a pint. Gave them to a weak colony.

I VALUE supply-dealers more than I did. This spring I wanted some more feeders in a hurry, and had the stuff cut here because I thought I hadn't time to send to Medina. I found, after I had them made, that I could have ordered them by telegraph, and had them sent by express ready made, at less expense than the stuff ready to nail cost me here.

PROF. COOK, speaking of a law against spraying fruit-trees while in bloom, says, on p. 323, "I do not think such a law would need to be used much, if ever; but as an educator it would do signal service." Don't you think it would be a good thing, professor, to have a law to prevent my planting an apiary on ground fully occupied by you, not to be used much, you know, "but as an educator"?

I WONDER if, for once, Doolittle hasn't got things a little mixed when he speaks on p. 326 about bees gnawing foundation when put on too early. I generally put on sections before bits of white wax are seen—not because it is better, but because it suits my convenience better—and I never observed any foundation gnawed at that time, but I've had foundation badly gnawed after storing ceased. Still, I may not have observed closely enough before harvest.

MRS. AXTELL properly raises the question, "If hybrids are really as good honey-producers as the pure race, then why charge more for the pure?" Even if hybrids were as good as the pure, it does not follow that successive generations of hybrids would not deteriorate. Some dairymen think half-breed Jerseys as good as the pure; but they say their herds would rapidly deteriorate if they used only half-breeds for breeding.

THE WIGGLING that Mrs. Axtell talks about on p. 324, is, I think, entirely different from the back and forward "raking" spoken of in *C. B. J.* The "wiggling," I have oftenest seen by bees on the comb; the "raking," never anywhere except on the outside of the hive. Lately I have seen it suggested that bees wriggle in this way in order to help them disgorge the contents of the honey-sac. But there doesn't seem enough of it for that.

EXPERIMENTS IN APICULTURE; HISTORY AND SUGGESTION.

PROF. COOK GIVES AN OUTLINE OF WHAT HAS BEEN DONE.

Dear Mr. Editor:—The subject of experiments in bee-keeping is one that has taken much of my thought for years; and so the article in the current volume of GLEANINGS, p. 228, from the able pen of one of our most expert bee-keepers, the late president of the American Association, was read with no slight interest. I am glad that he and the American Association are moving in this direction. I believe he is the chairman of a committee to look after this matter. I am glad that this is so. Such action is wise. I believe the government, which is looking after the interests of almost all industries in very telling ways, should not overlook that of bee-keeping. I am also quite certain that, if bee-keepers demand recognition, and ask aid, the government will not be slow to render all possible assistance.

HISTORY.
